THE EVOLUTION OF ENGINEERING TEAMS

Why Engineering Never Seems To Build "The Right Thing"

A Systems Explanation of Why It's So Damn Hard

A field guide for non-engineers and new managers, in stick figures.

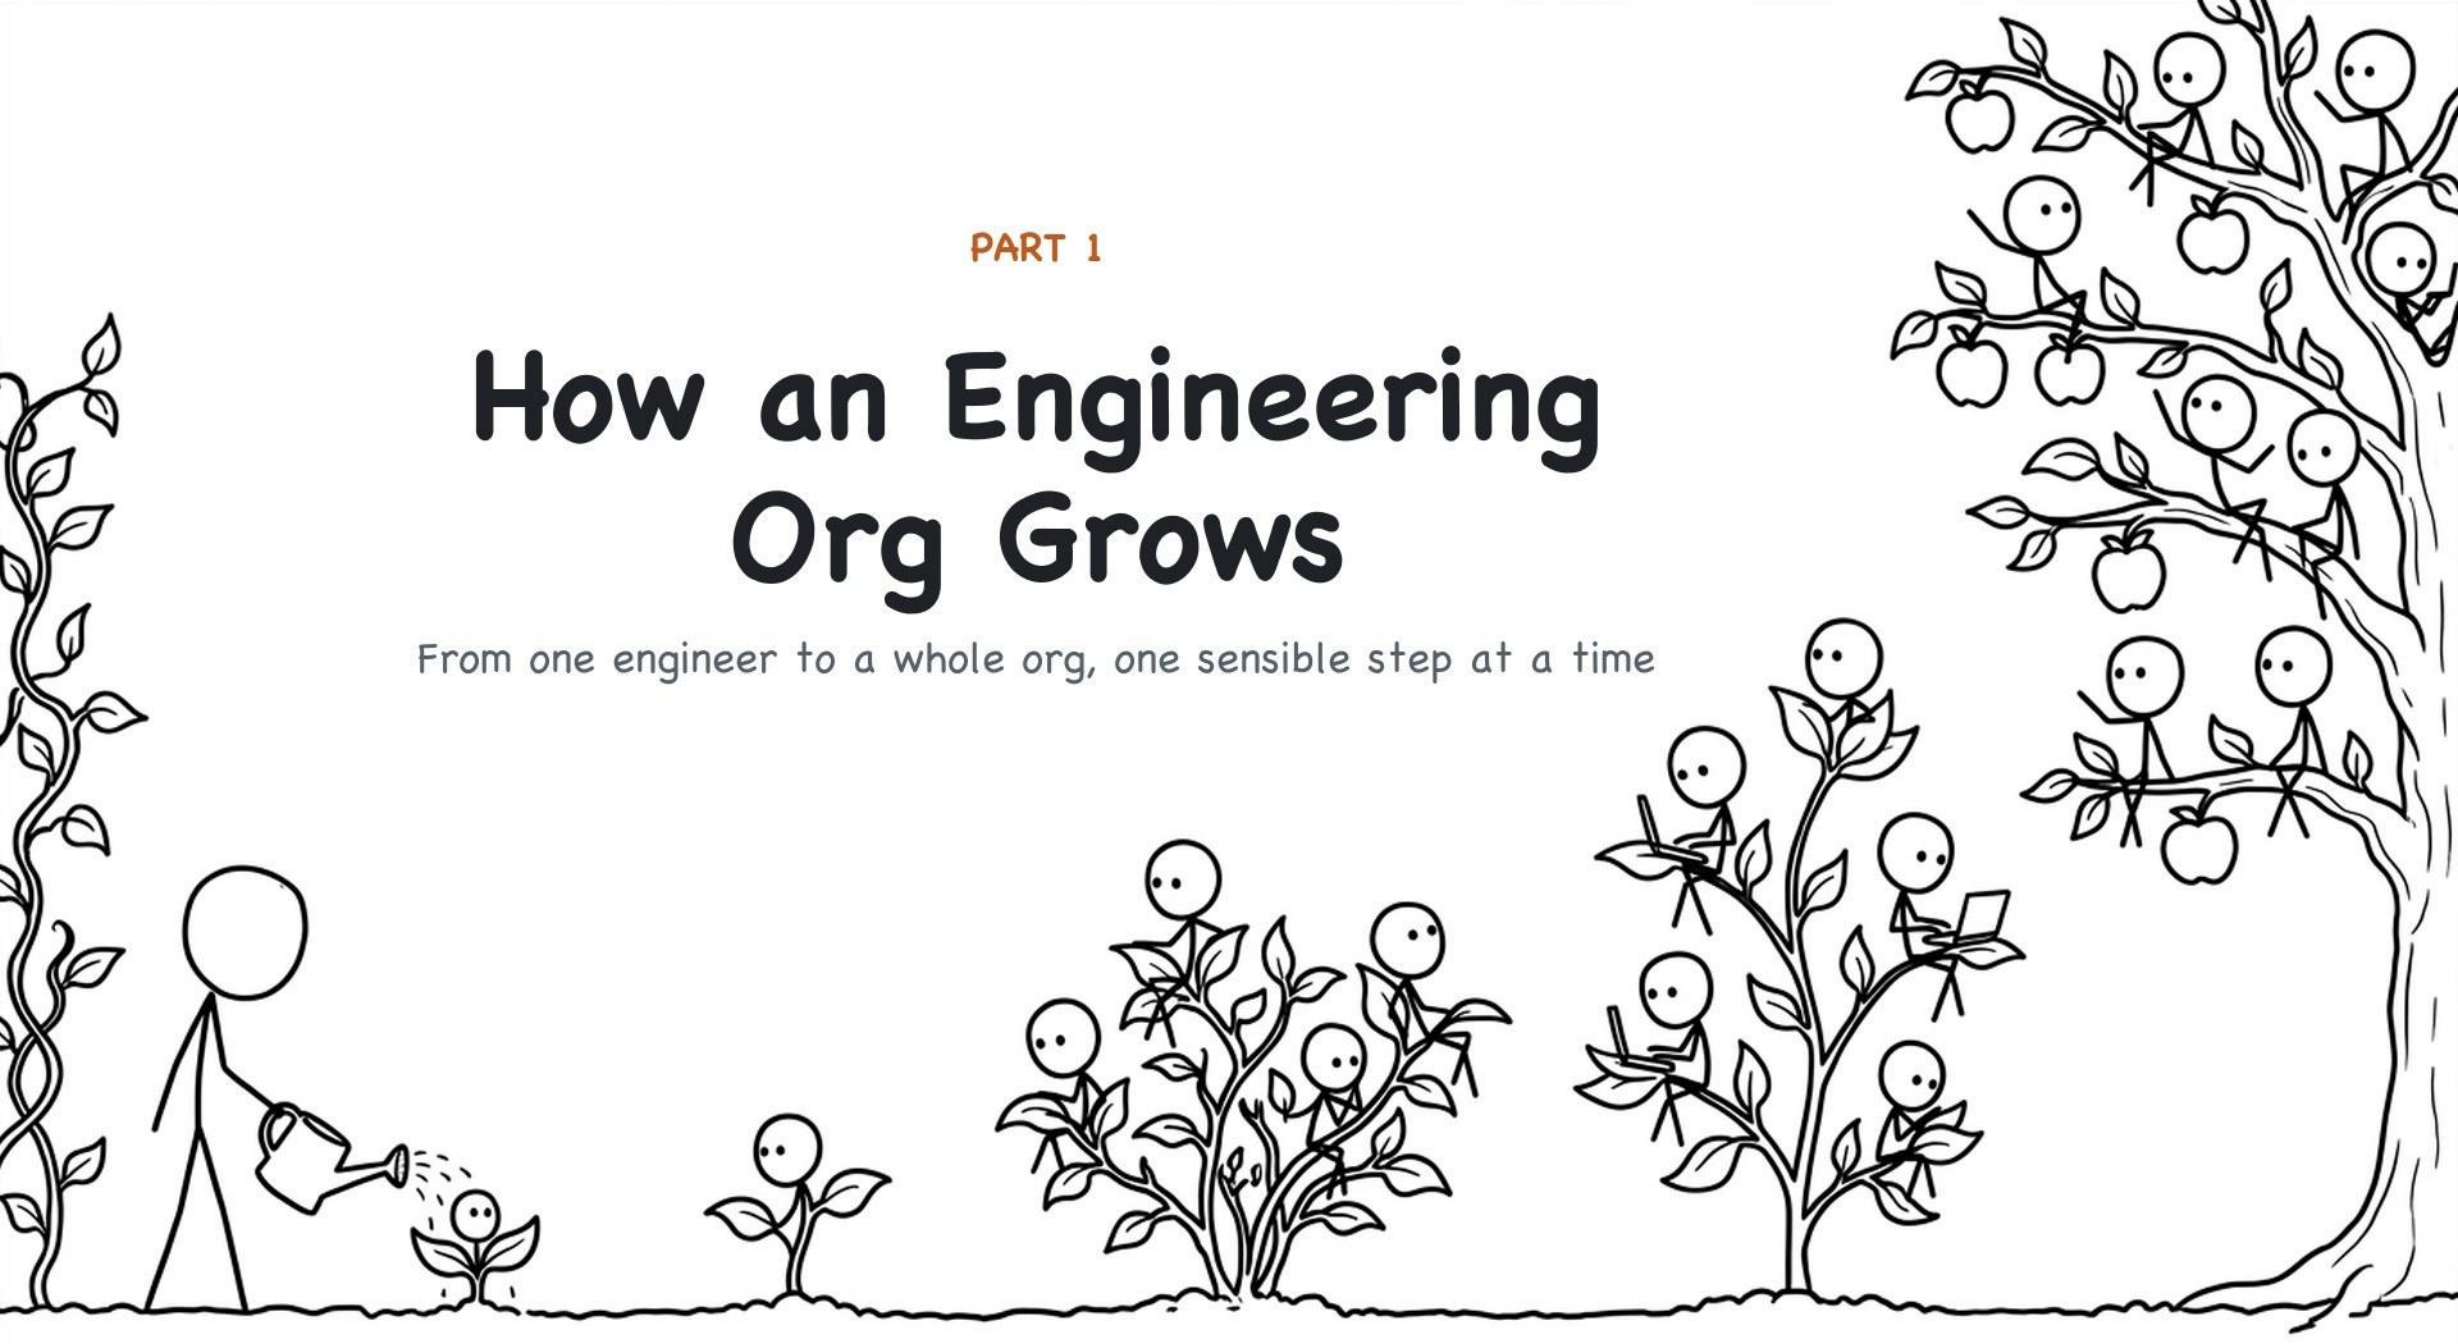

Opening. Who this is for: people who work with engineering teams but haven't been inside one, and new managers who want the "why" behind how these teams behave.

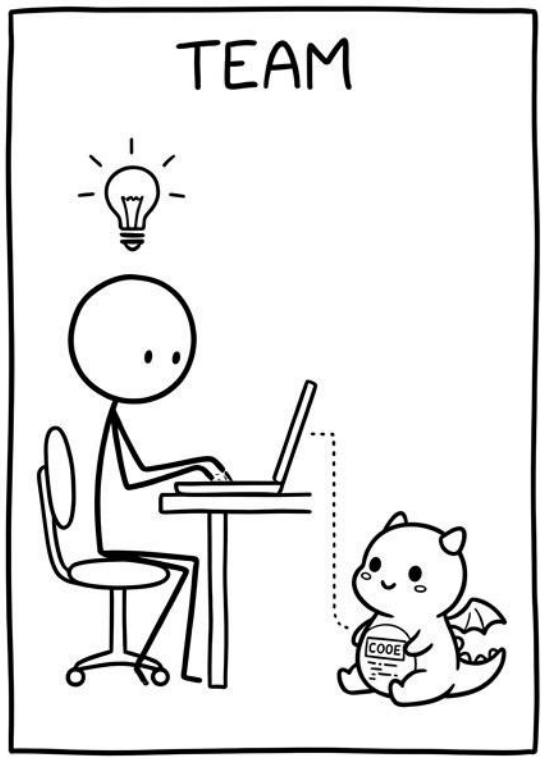

PART 1

How an Engineering Org Grows

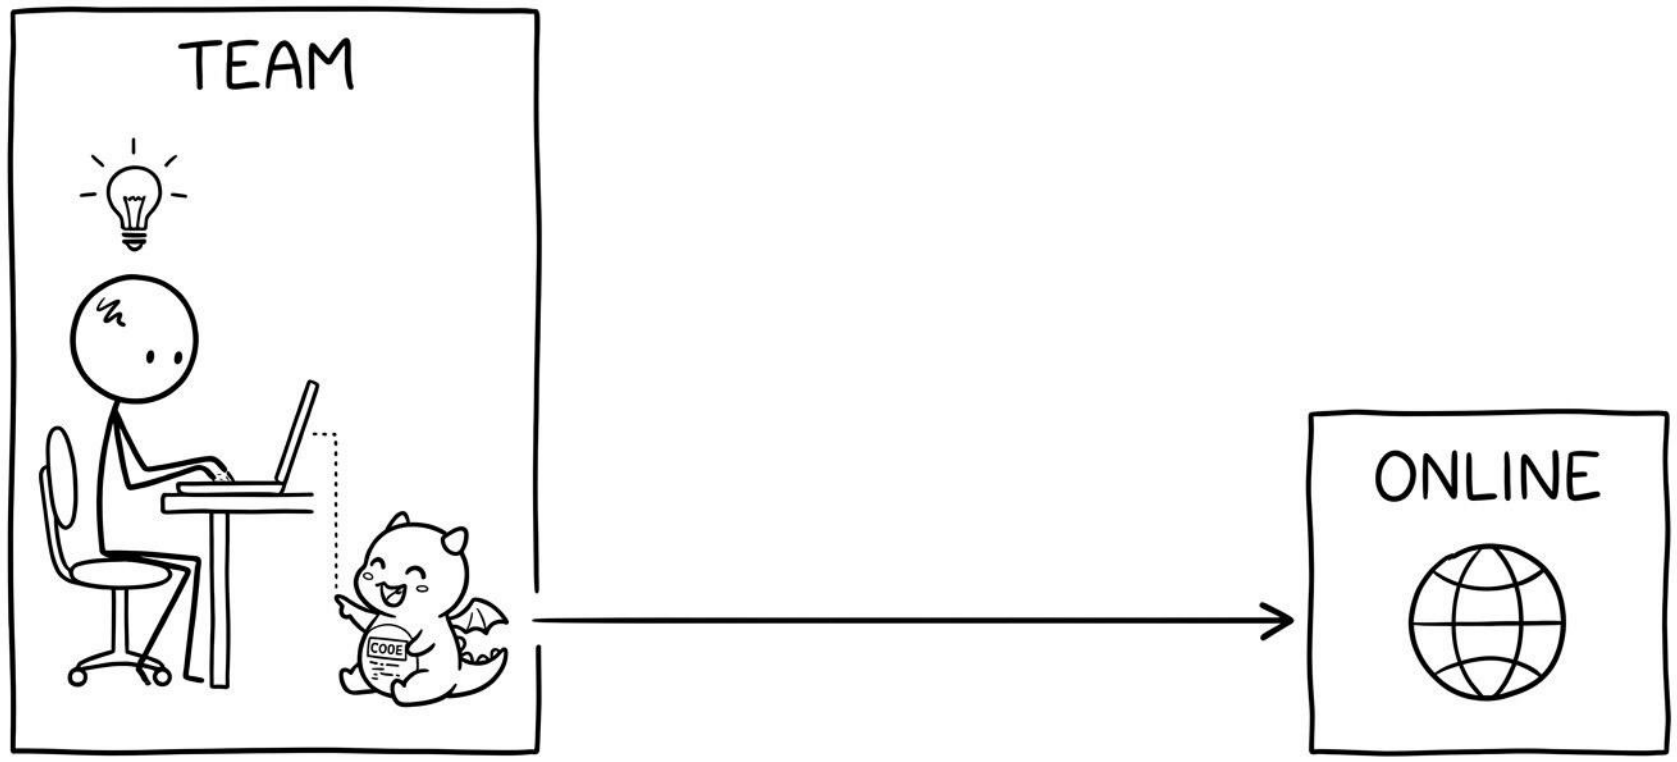

From one engineer to a whole org, one sensible step at a time

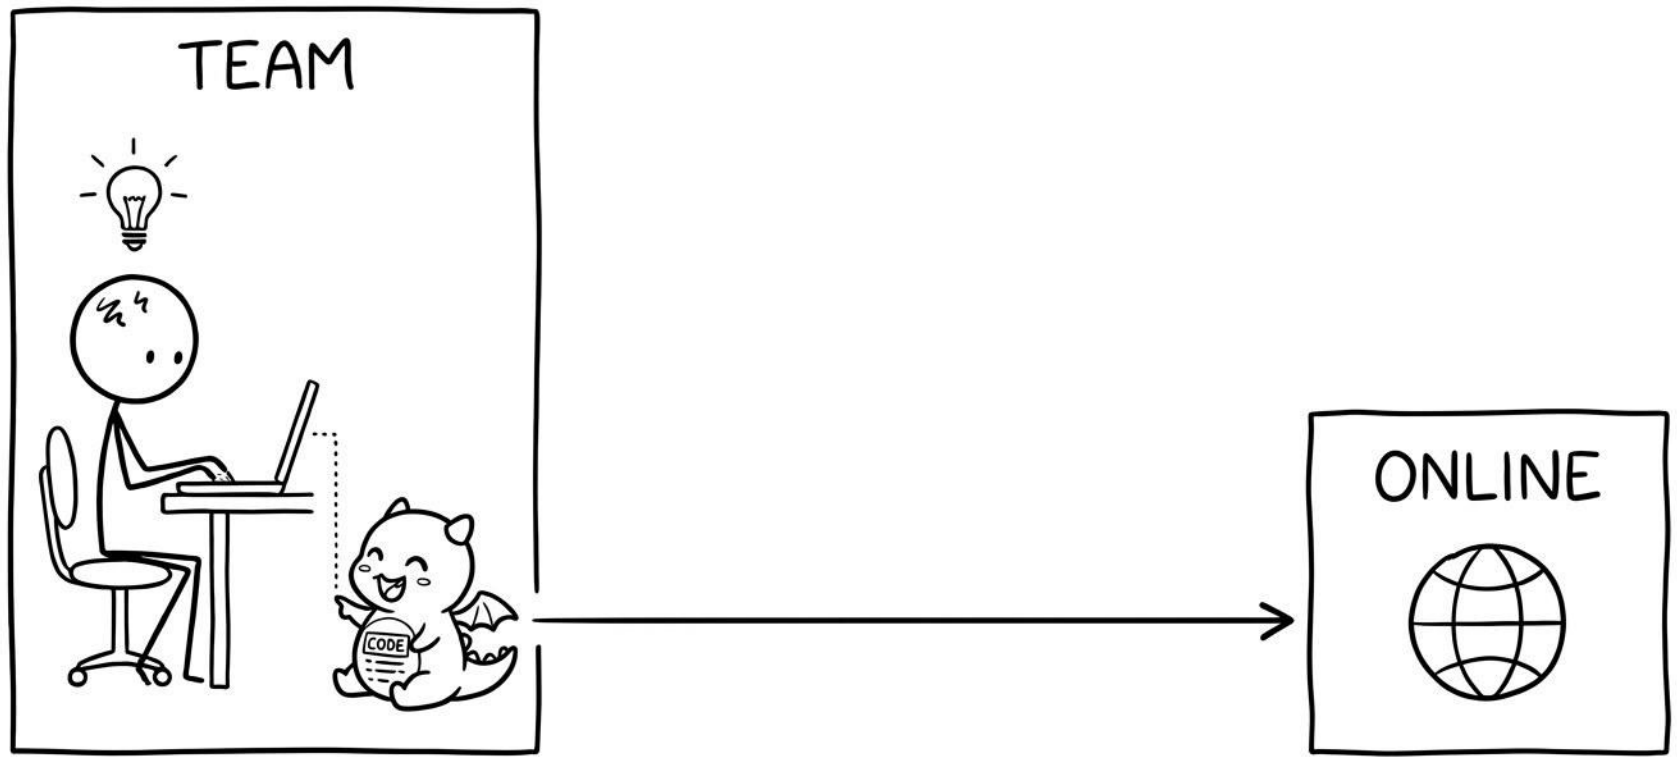

Part 1: How an Engineering Org Grows. First, how a team grows: from one person with an idea to a whole organisation. Every step along the way is a sensible fix for a real problem.

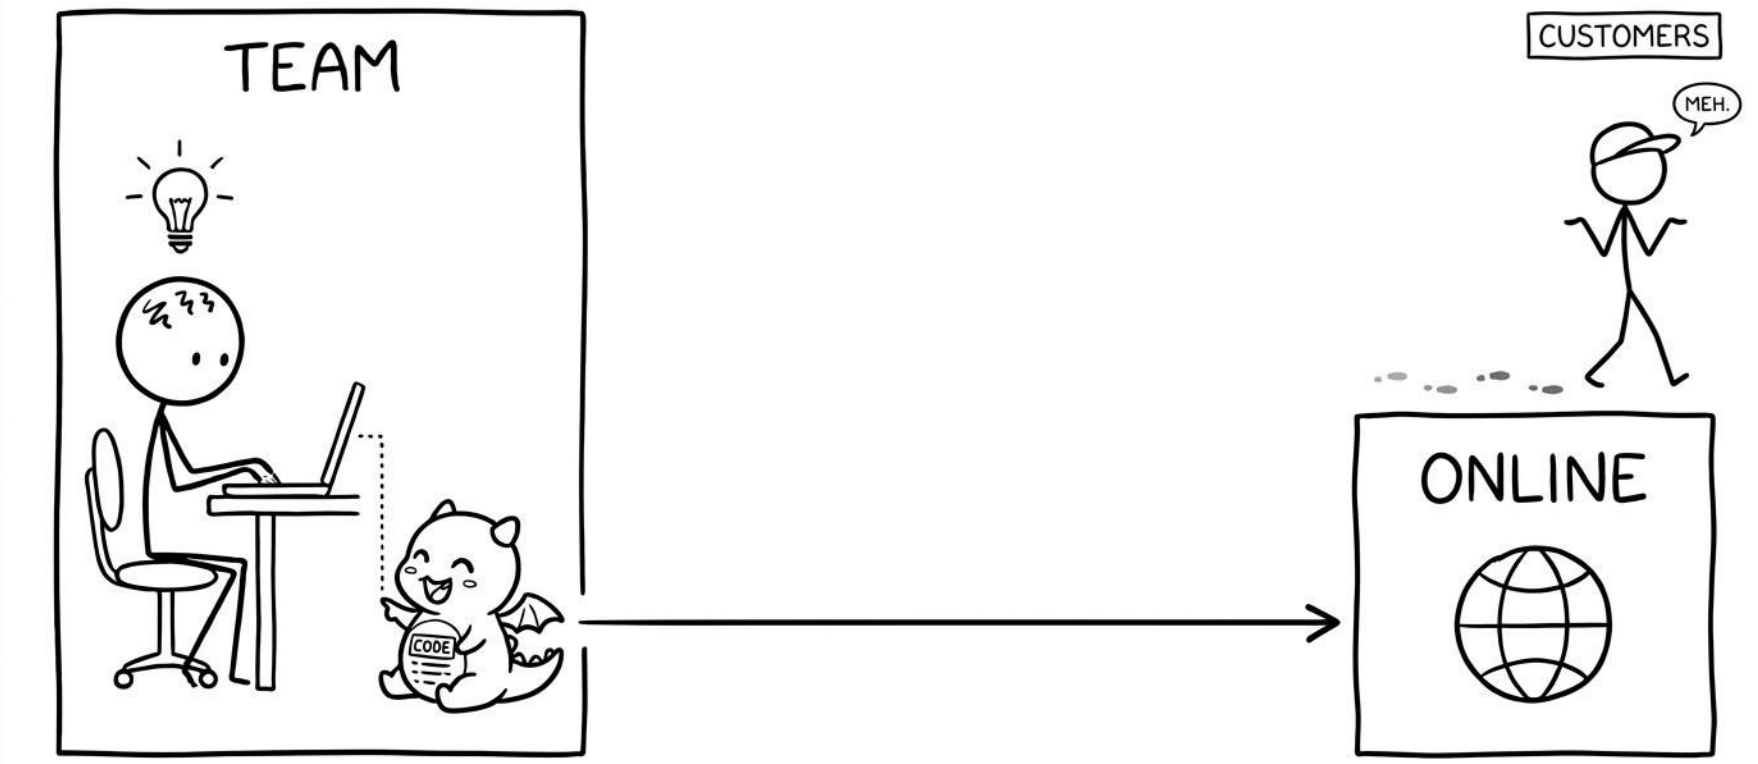

One engineer, one idea. State 1. One engineer, one idea, and the code they make: a cute little dragon. Remember the dragon. It grows.

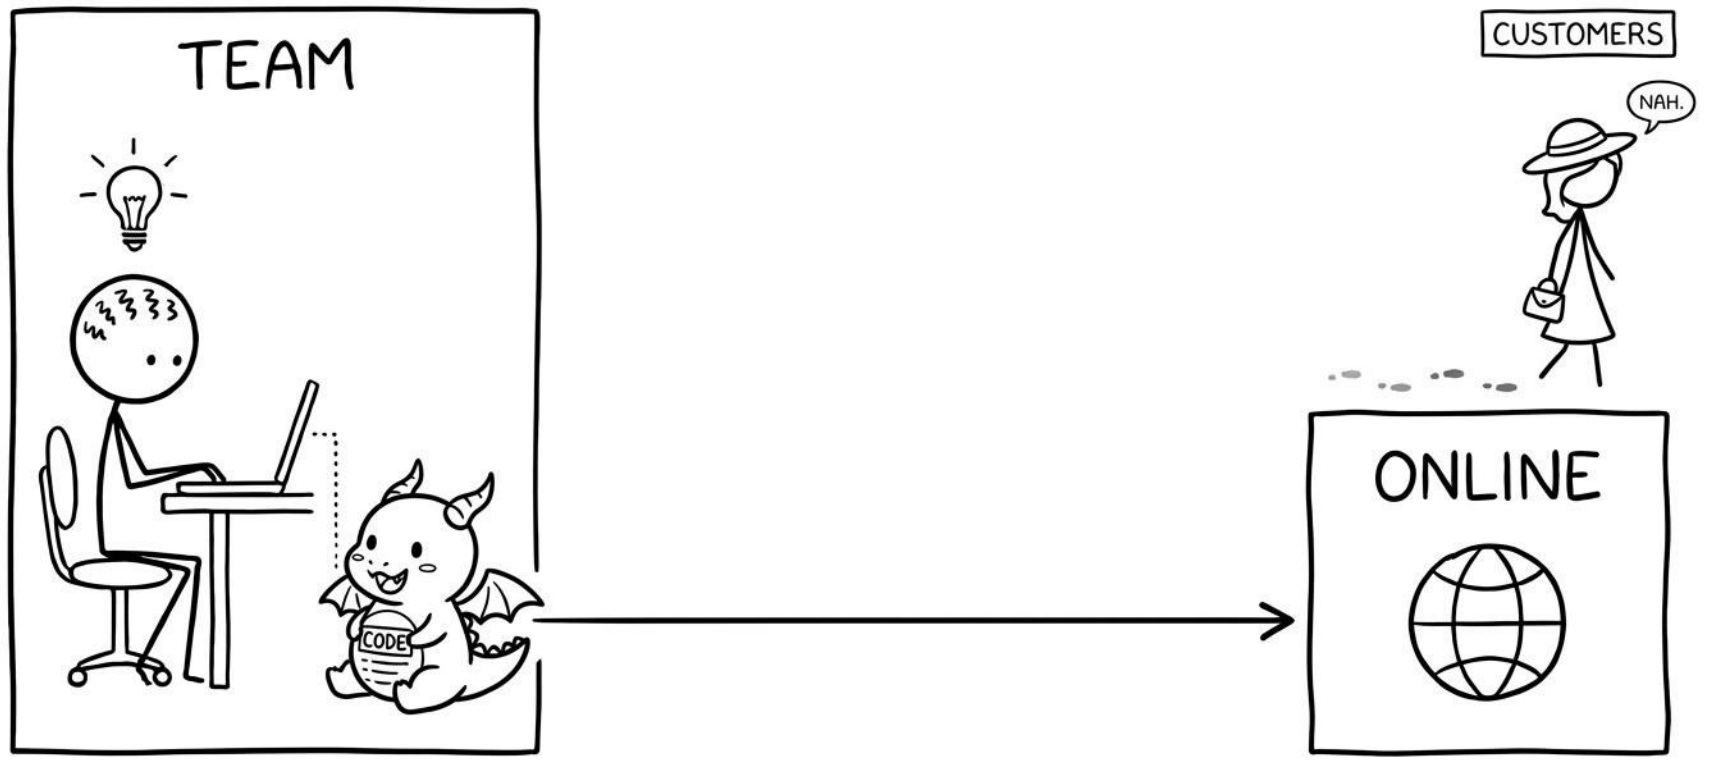

Putting it online. State 2. What changed: the engineer just puts the code online. No testing, no release process, no customers yet.

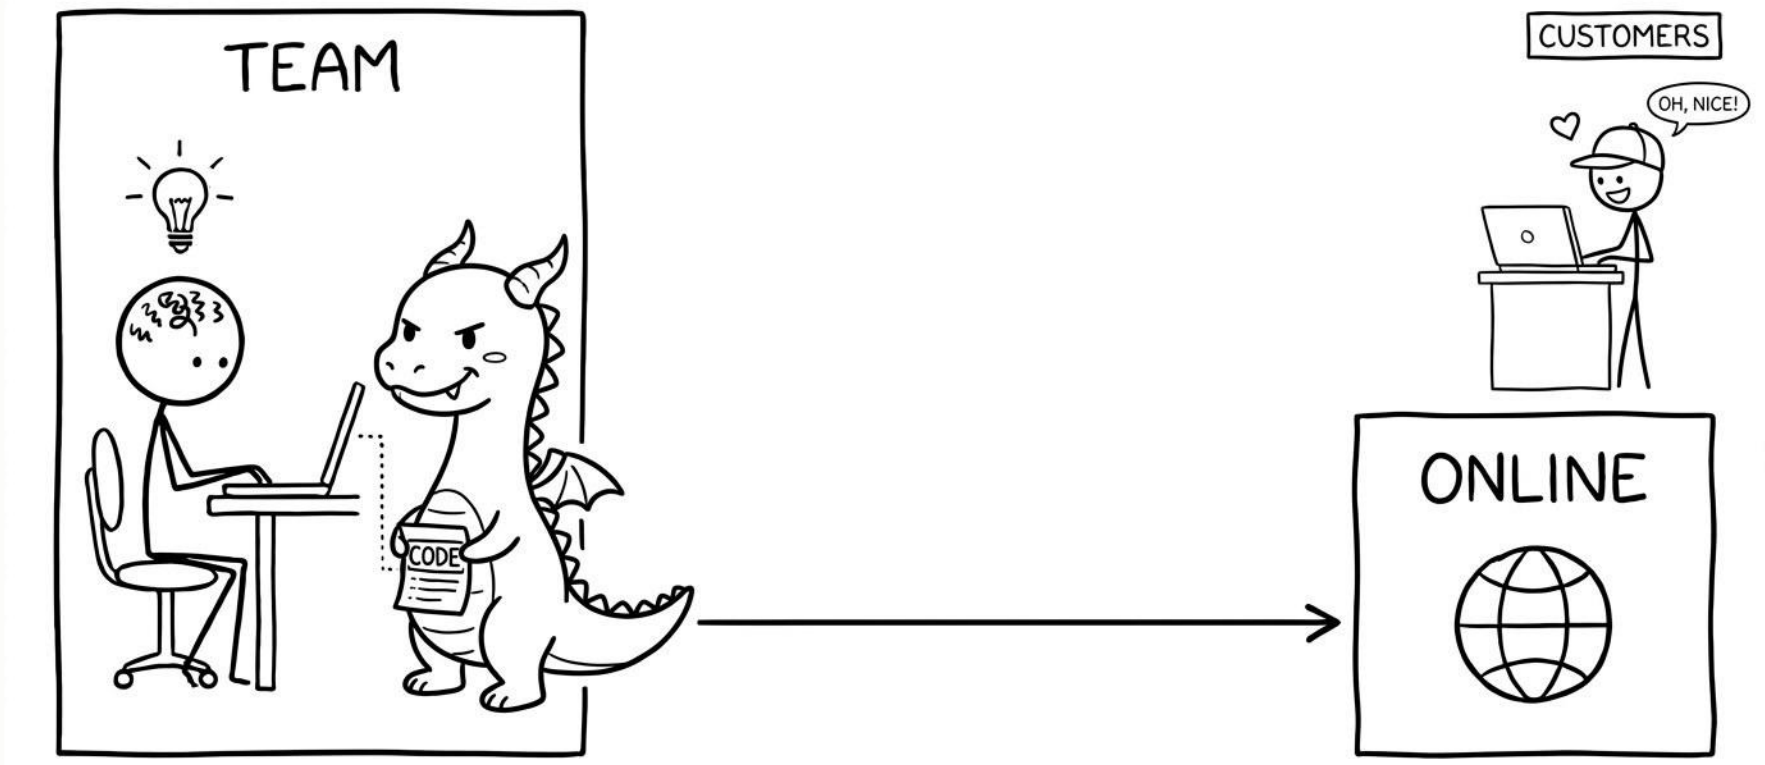

Building it out. State 3. What changed: the code grows, and so does what the engineer has to keep in their head. Still just a couple of squiggles.

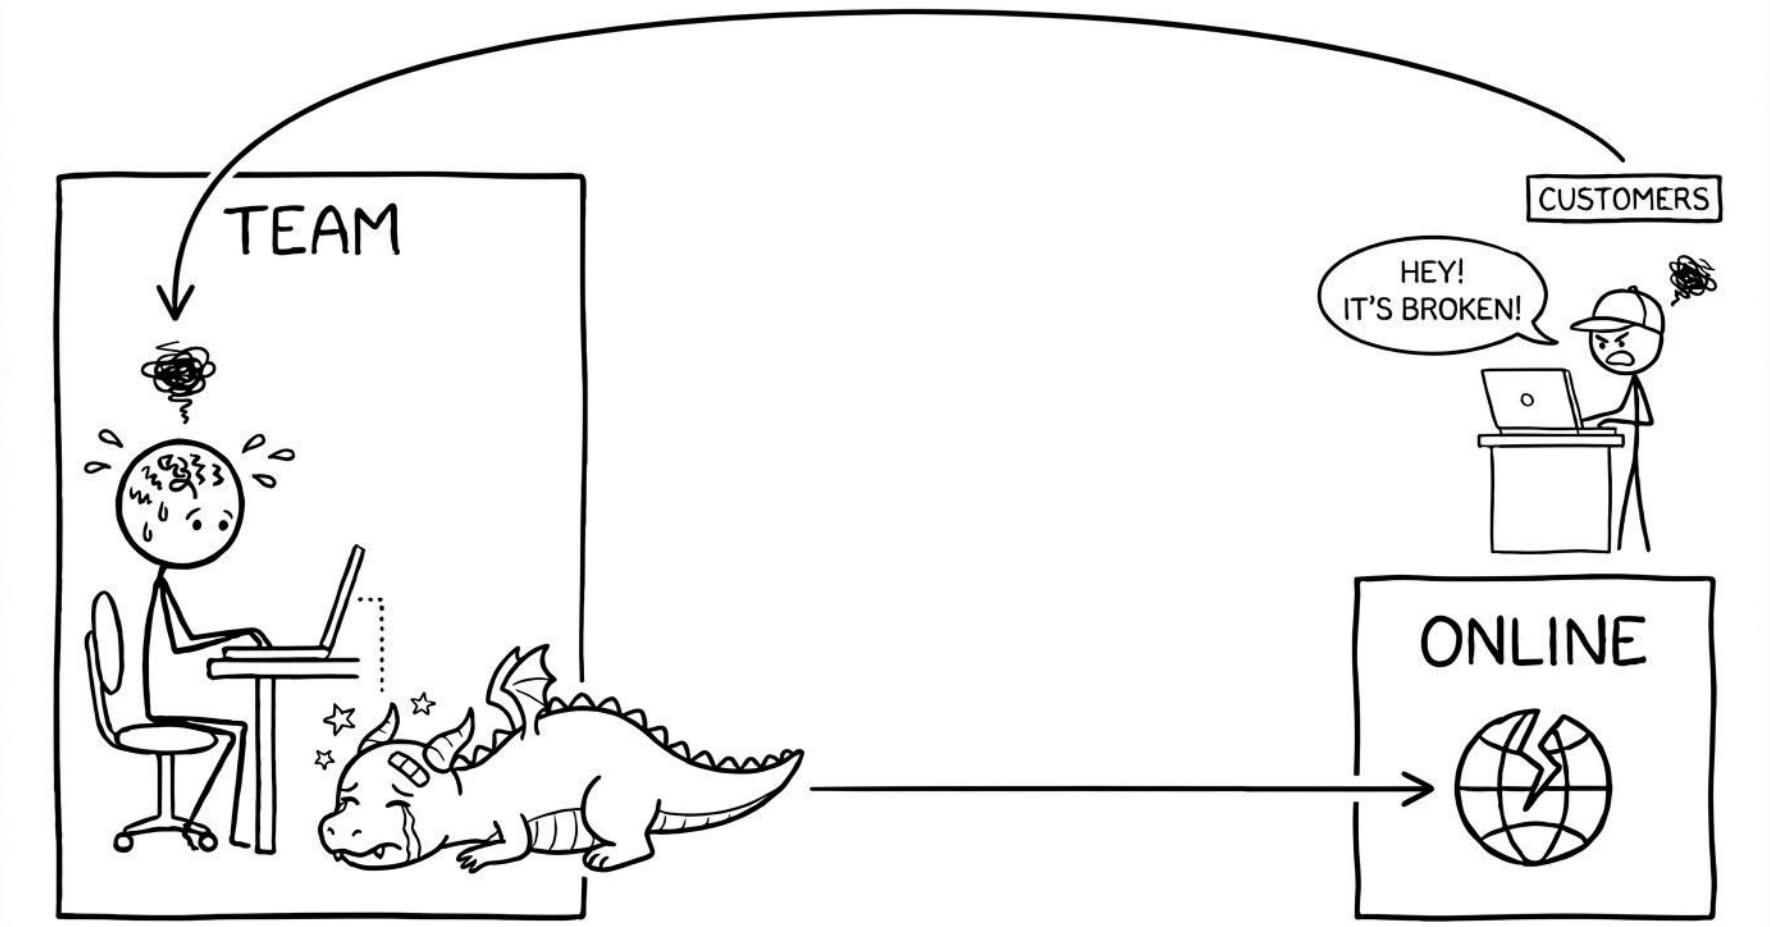

A visitor... who leaves. State 4. What changed: the first visitor shows up, looks, and leaves.
Most early products go through several rounds of this before anyone stays.

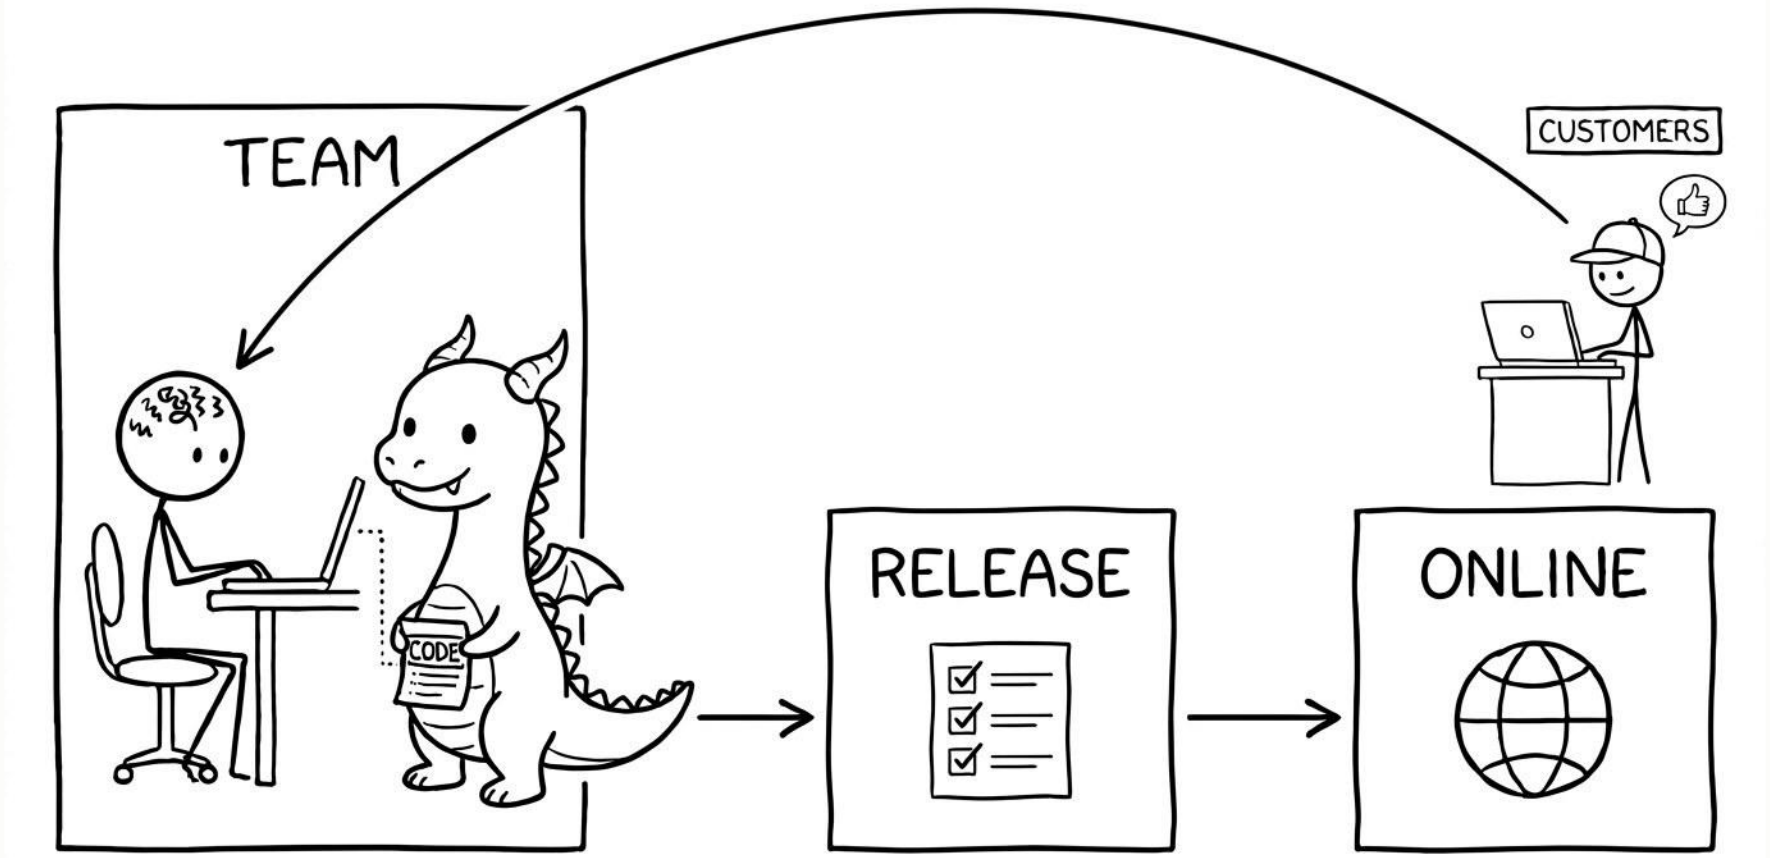

Build more, try again. State 5. What changed: more building, another visitor, another "nah."
The code keeps growing even when nobody is using it yet.

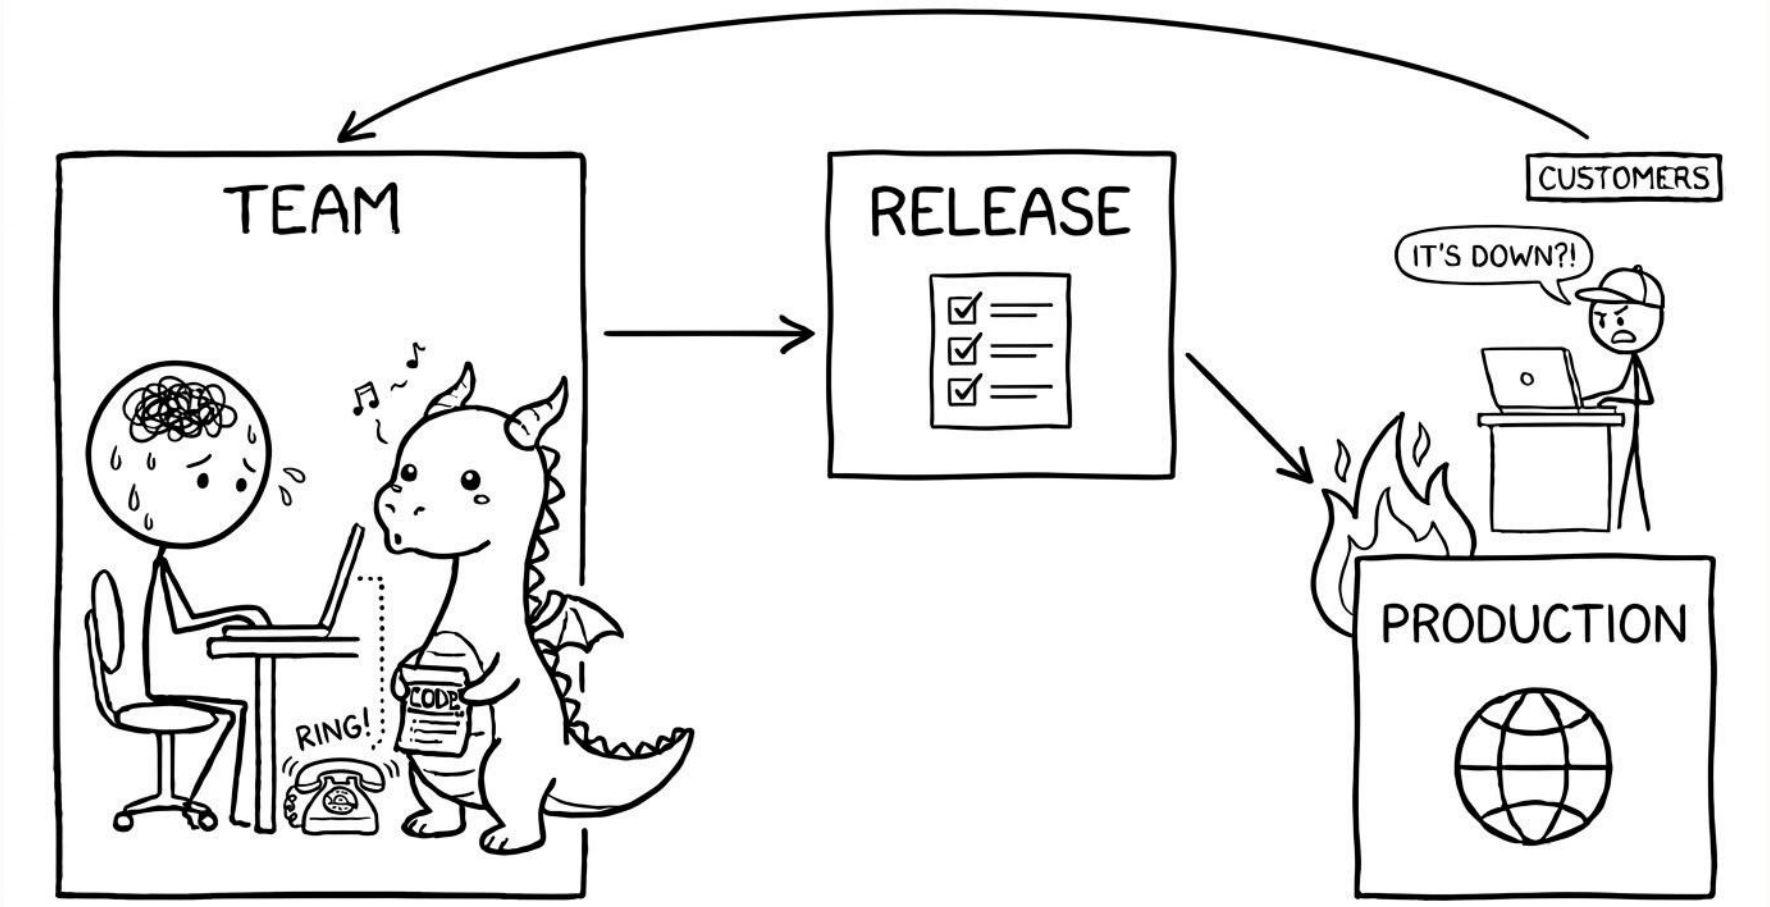

A customer stays. State 6. What changed: finally, someone stays. The code is a lot bigger now, and it's starting to have a personality of its own.

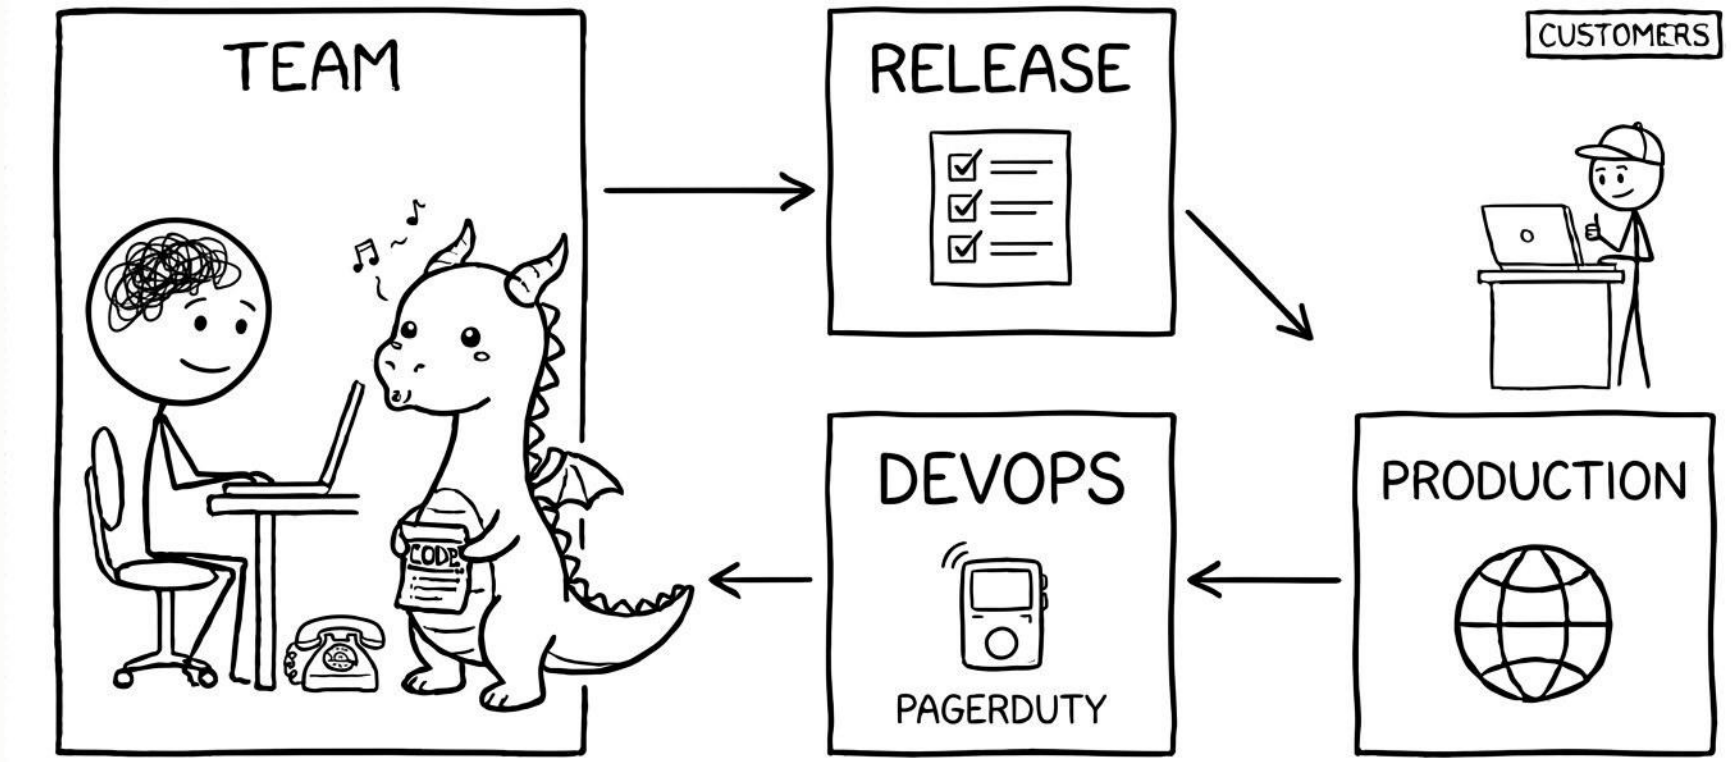

But the problem with having a customer is... they notice when you break things. This is the first feedback loop: customers complaining when things don't work. In a small team, it goes straight to the right person.

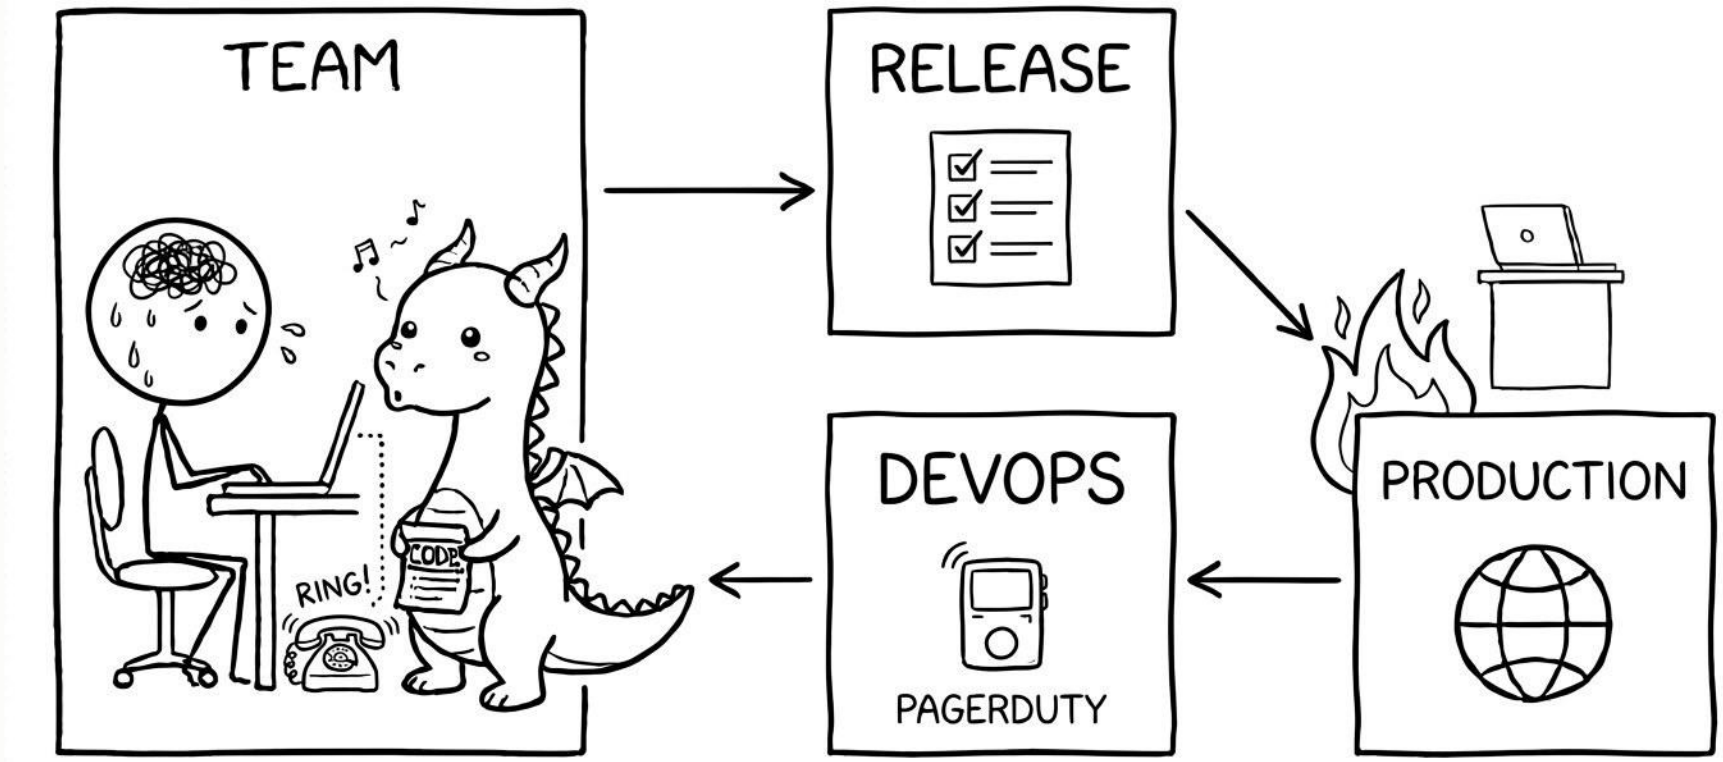

So our engineer adds a new step. This is usually some automated tests & extra code to make sure what is being pushed will actually work. We call this the "release" step.

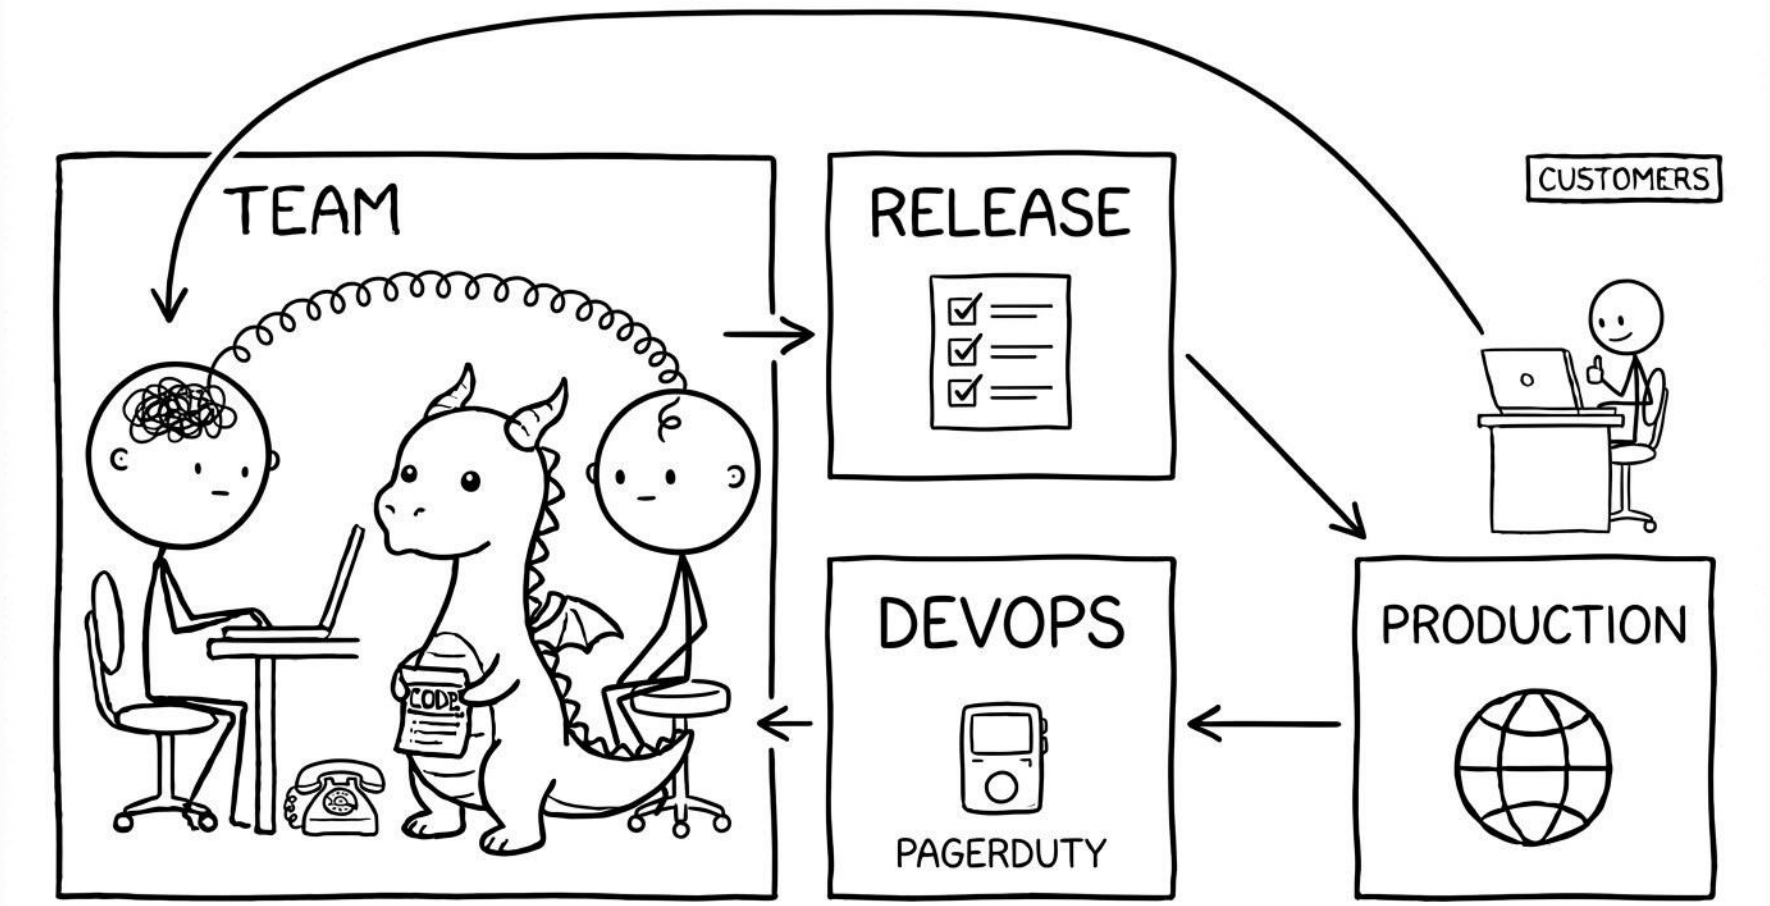

But releases don't guarantee things won't break. AWS could go down. The hardware could fail. There could be some nasty bug that takes down the whole service.

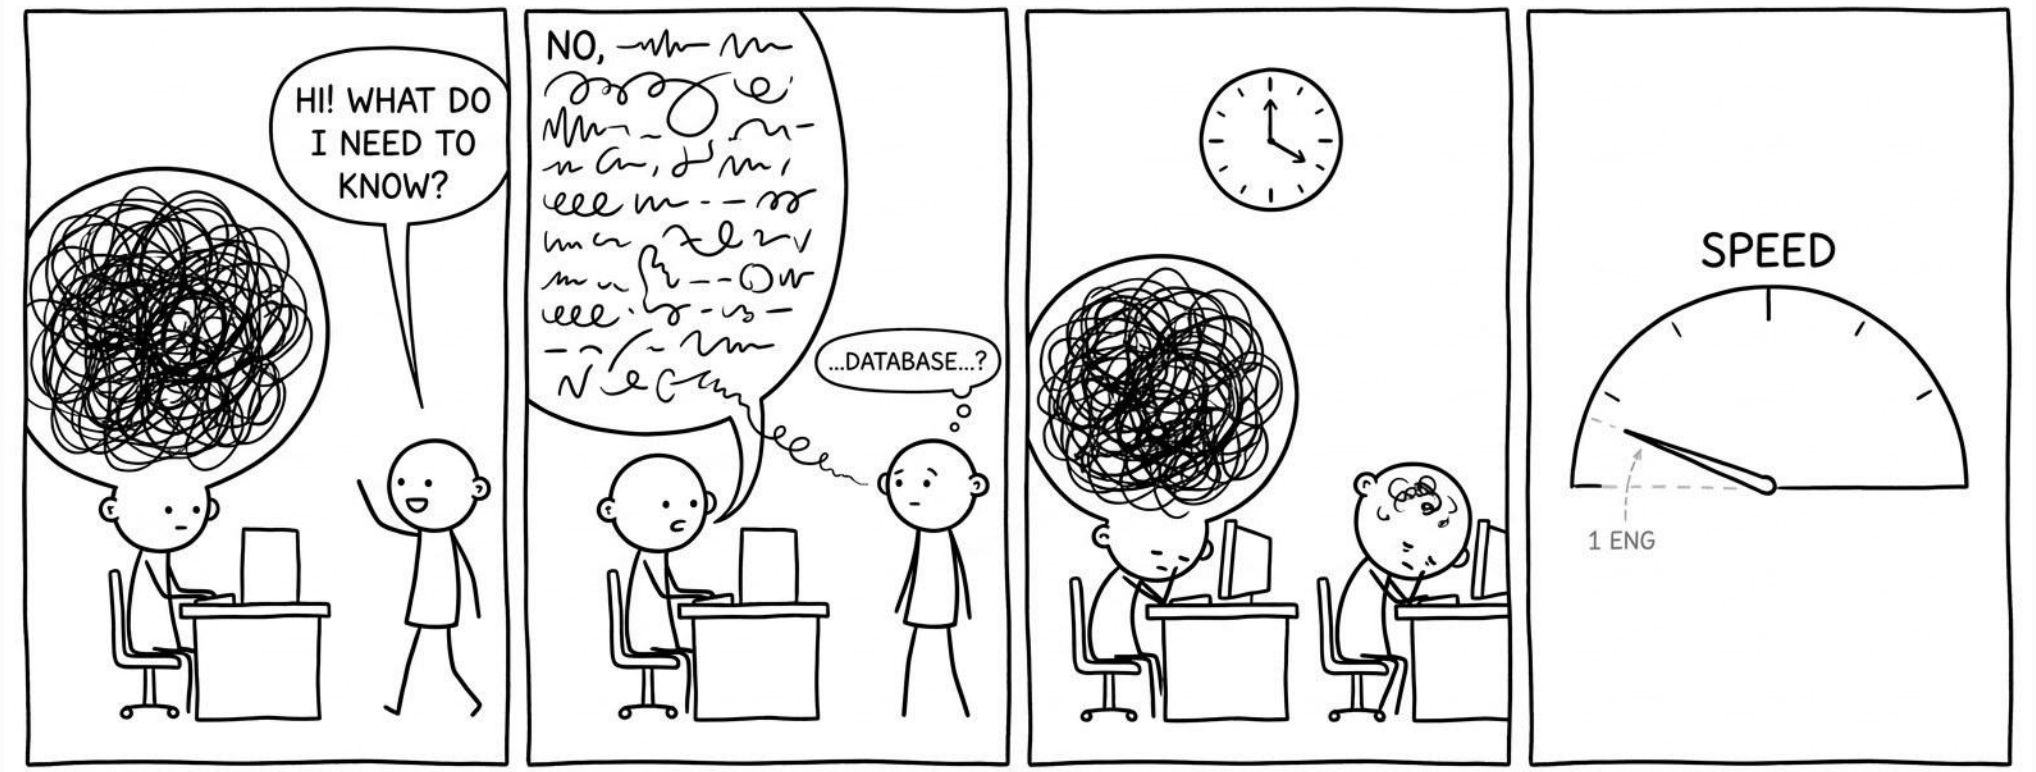

When this happens, engineers will add an automated monitoring and "call home" system. We use PagerDuty + Prometheus for monitoring.

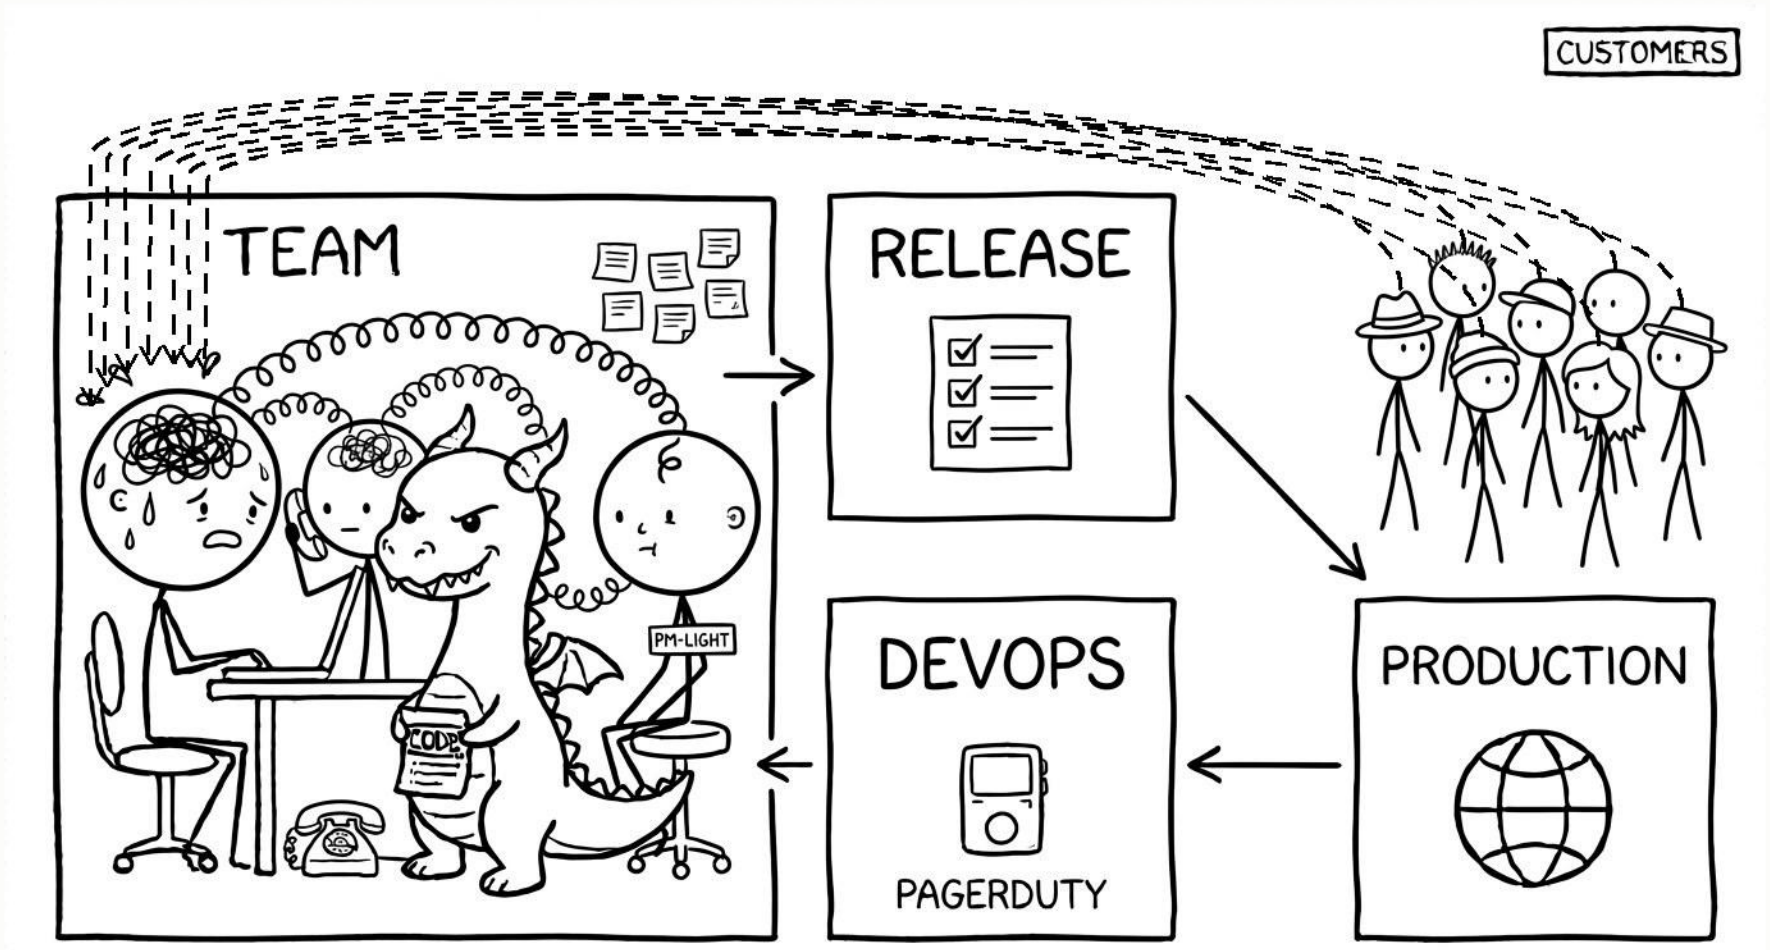

It breaks when nobody's watching. Slide 9c. What changed: production breaks with nobody using it. No customer complained, and the phone rings anyway, because the system now calls the engineer on its own.

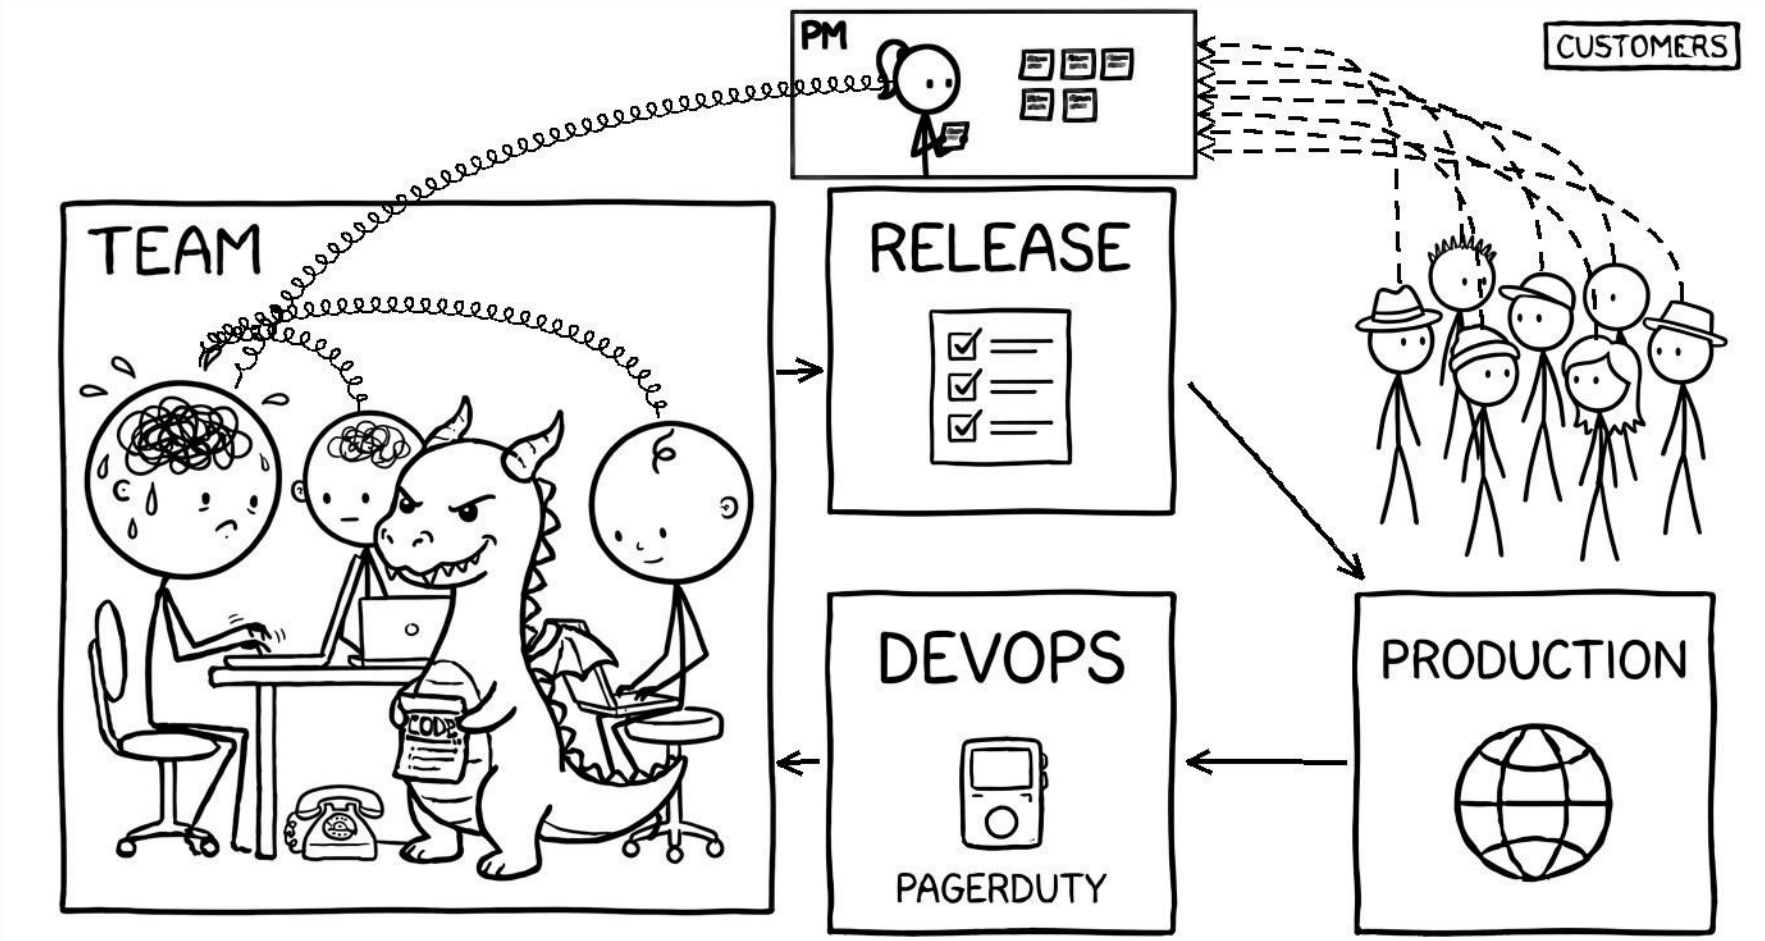

A second engineer. Slide 10. What changed: a second engineer joins with an almost empty head. Everything they need to know has to travel down one phone line from the first engineer's head. Small mouths, smaller ears. It's manageable, but it isn't free.

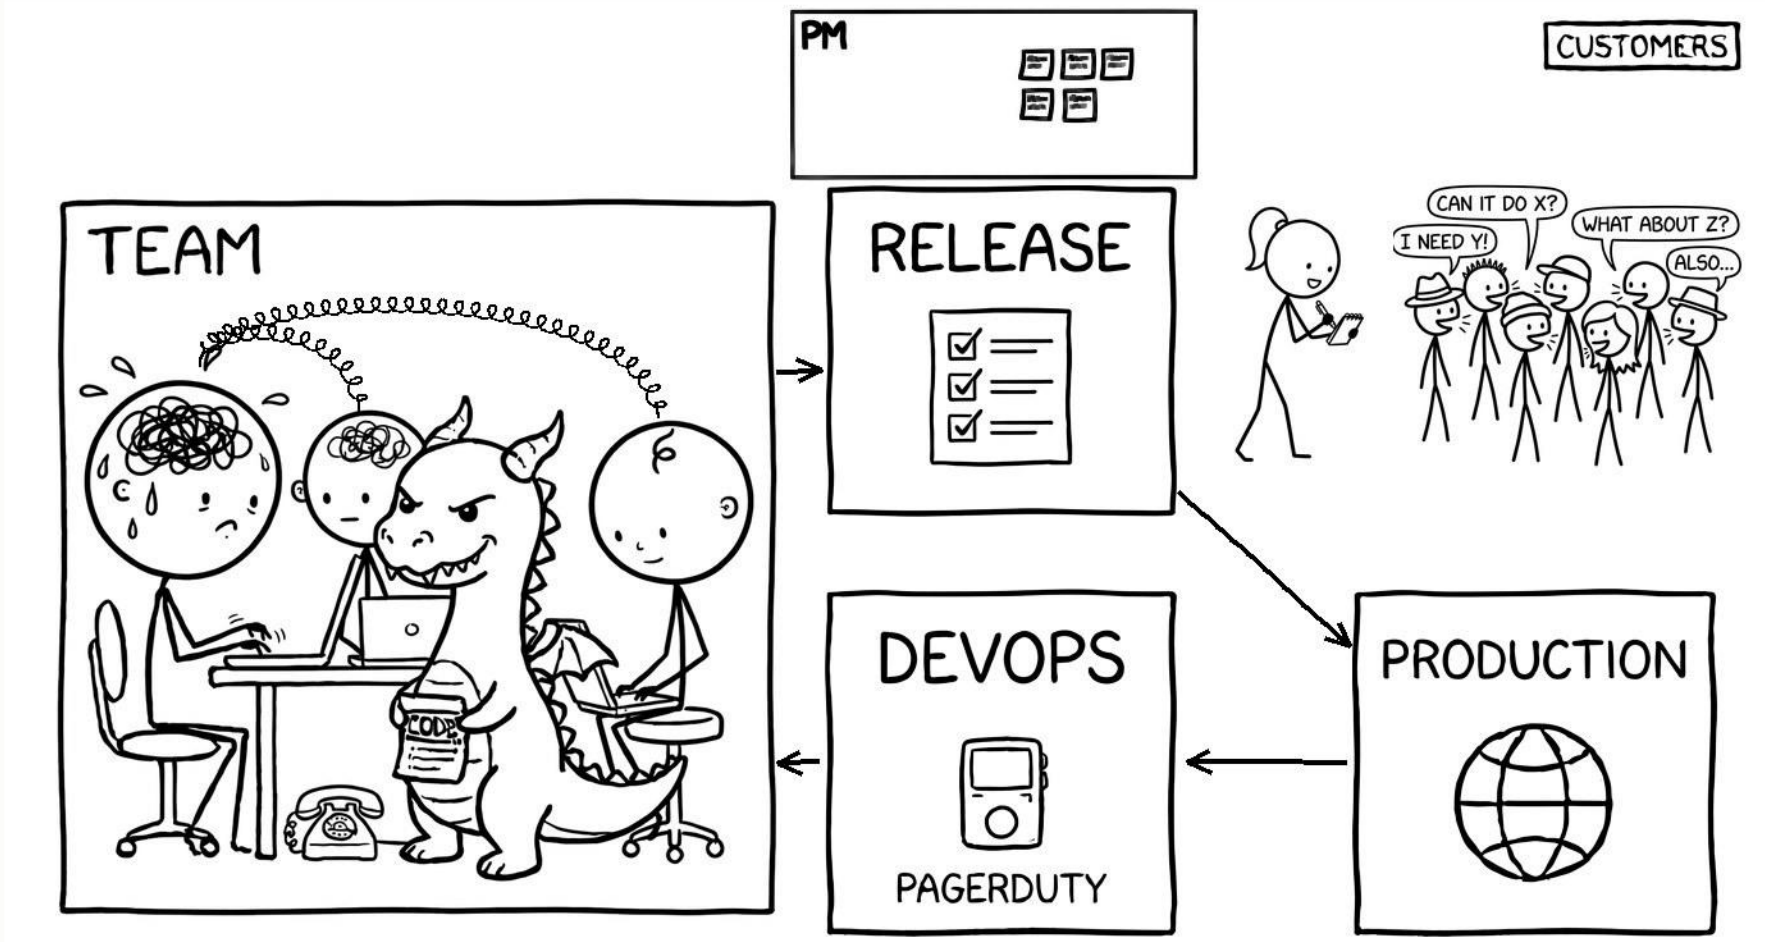

Two engineers ≠ twice as fast. Strip before state 5. Everything the first engineer knows lives in their head, and it only leaves through a small mouth into even smaller ears. The new engineer's ramp-up costs the old engineer's time, so speed barely moves at first.

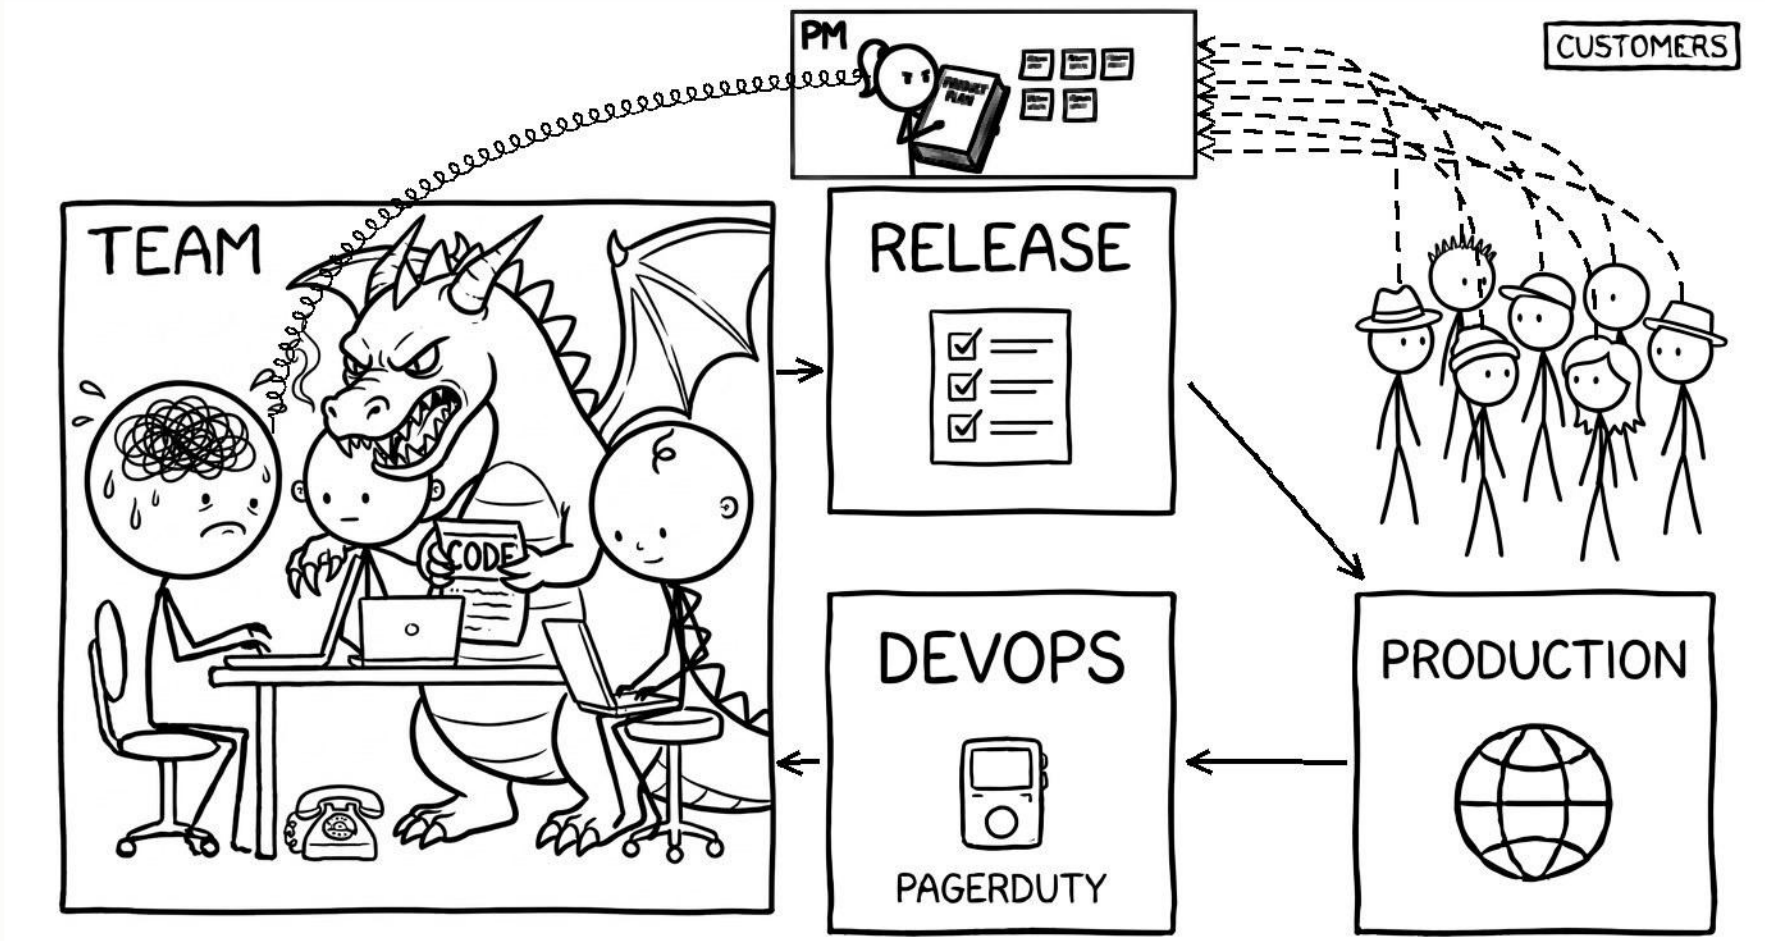

Phone lines multiply. Slide 11. What changed: four engineers and a handful of customers, and almost every line still runs to the original engineer, because everything is in his head. One engineer has started acting as a "PM-light" with a tiny backlog. The dragon is getting bigger, and a little less cute.

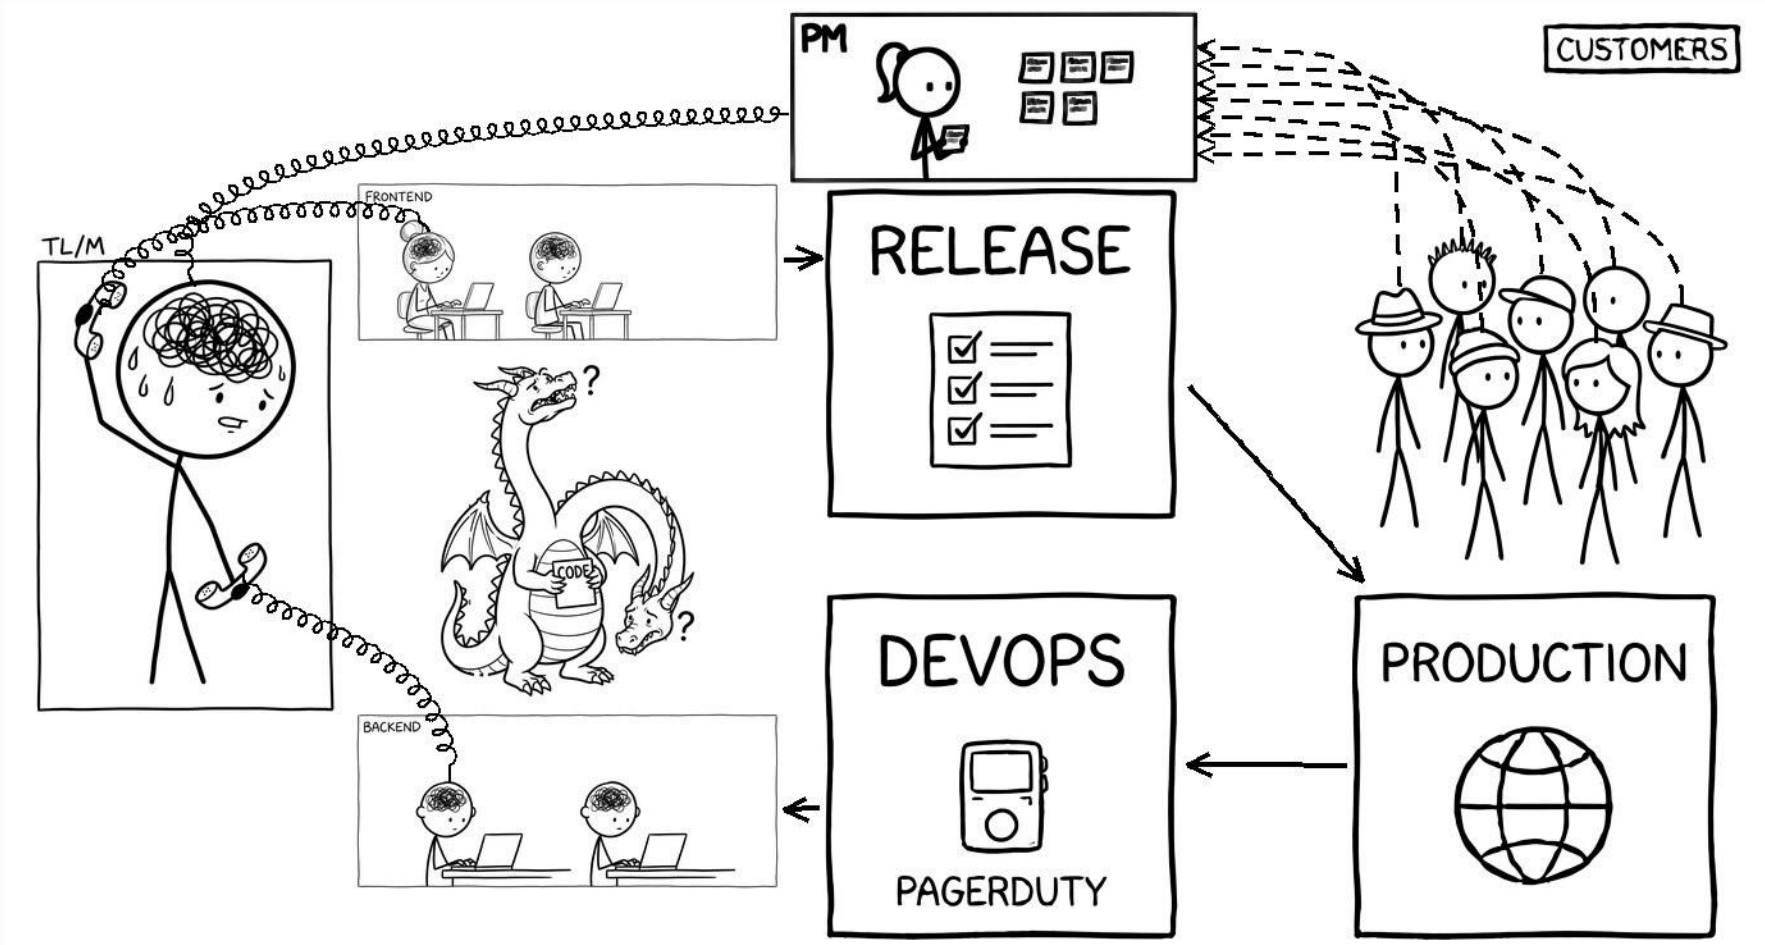

A Product Manager. What changed: the PM-light gets pulled out into their own job. Every customer now talks to the PM, and the PM has one line into the team. The main engineer gets some of his head back.

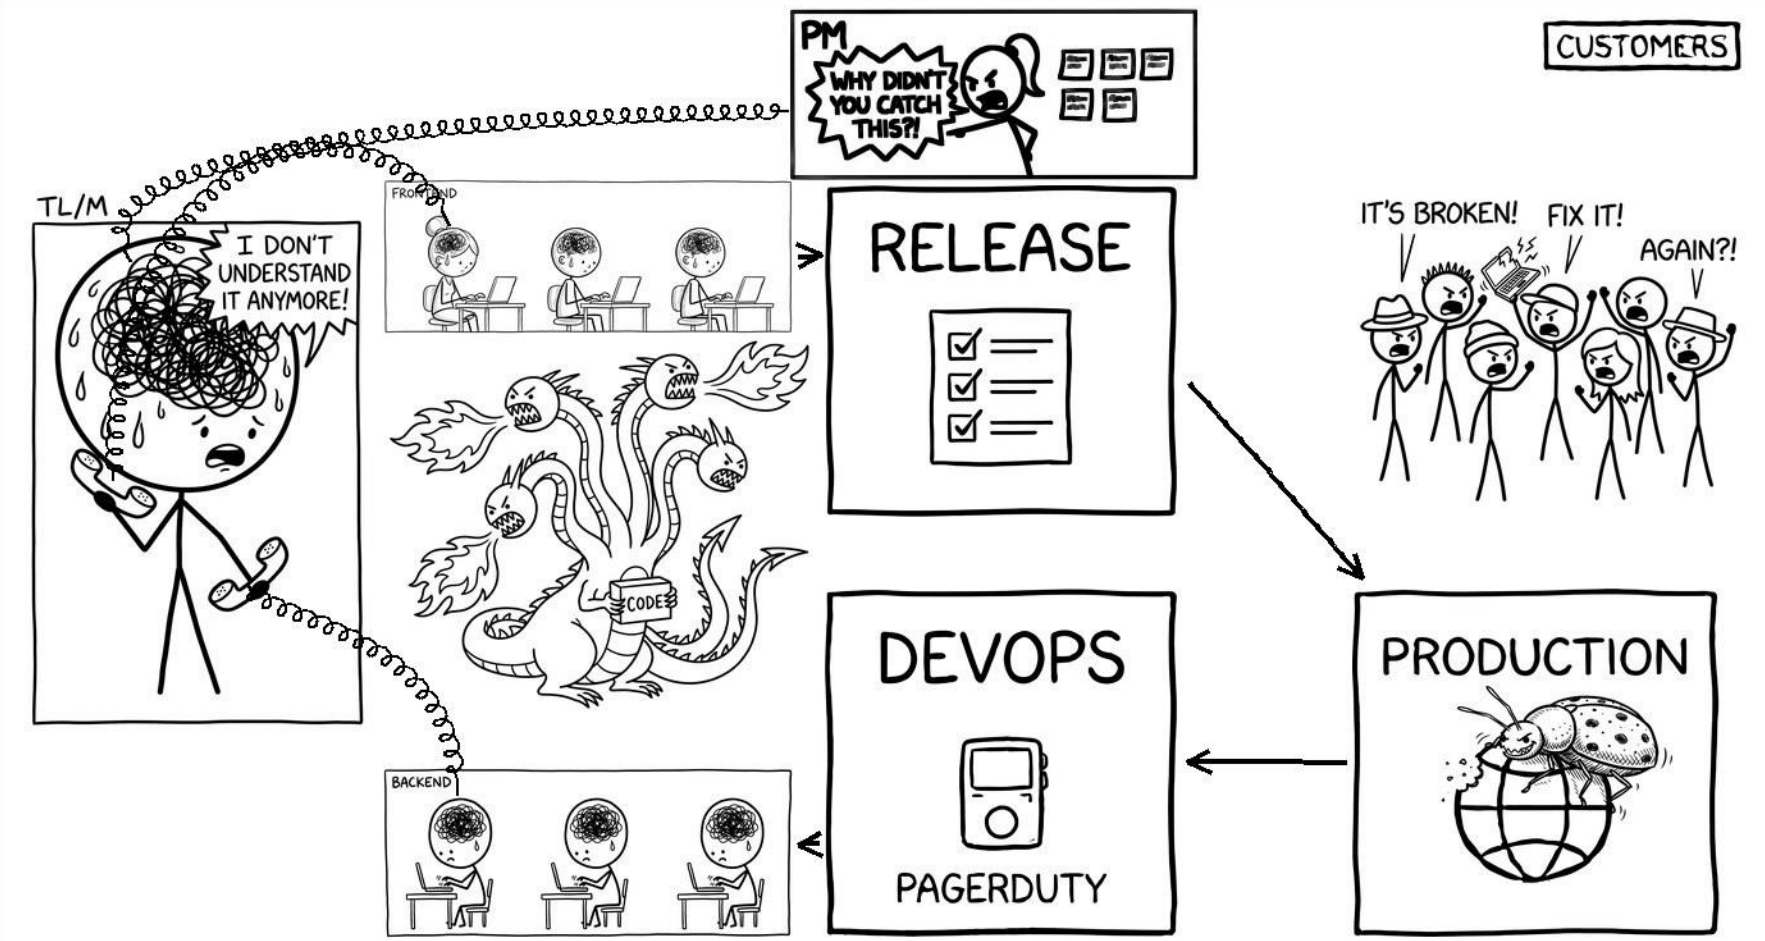

The feature loop: out with customers. The feature loop, part 1. The PM leaves the office and goes to the customers. Everyone has a request.

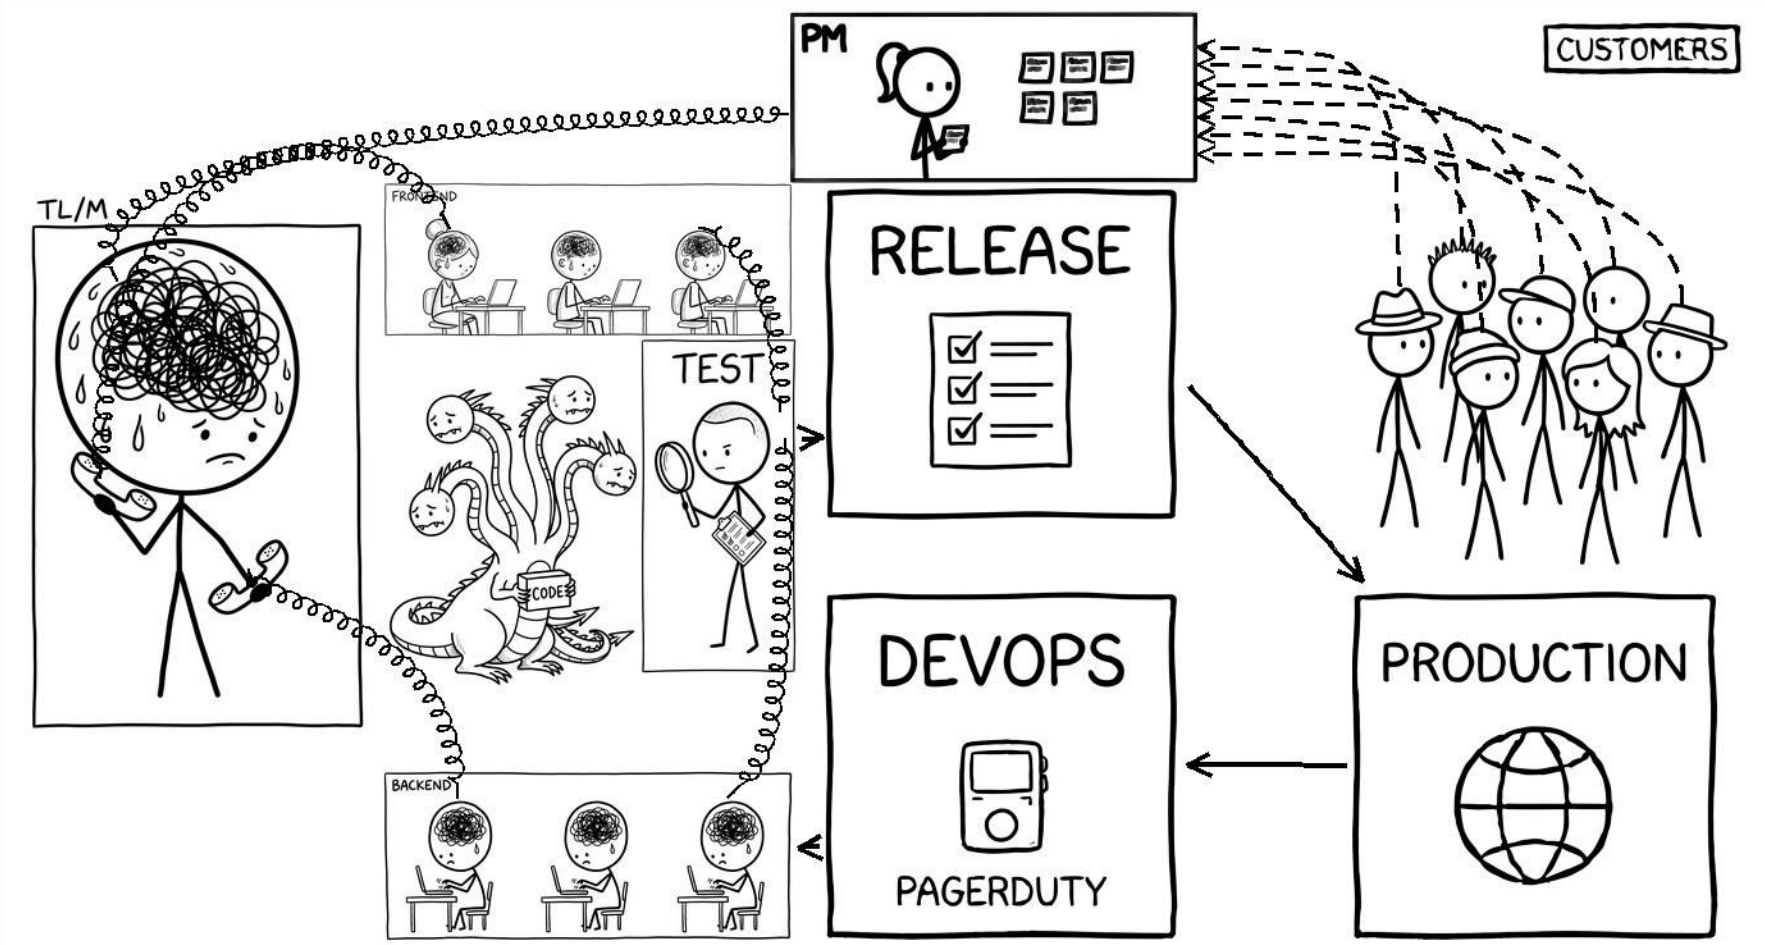

The feature loop: the Product Plan. The feature loop, part 2. The PM comes back with a very big book of things for engineering to build. One phone line into the team, and the book keeps getting thicker.

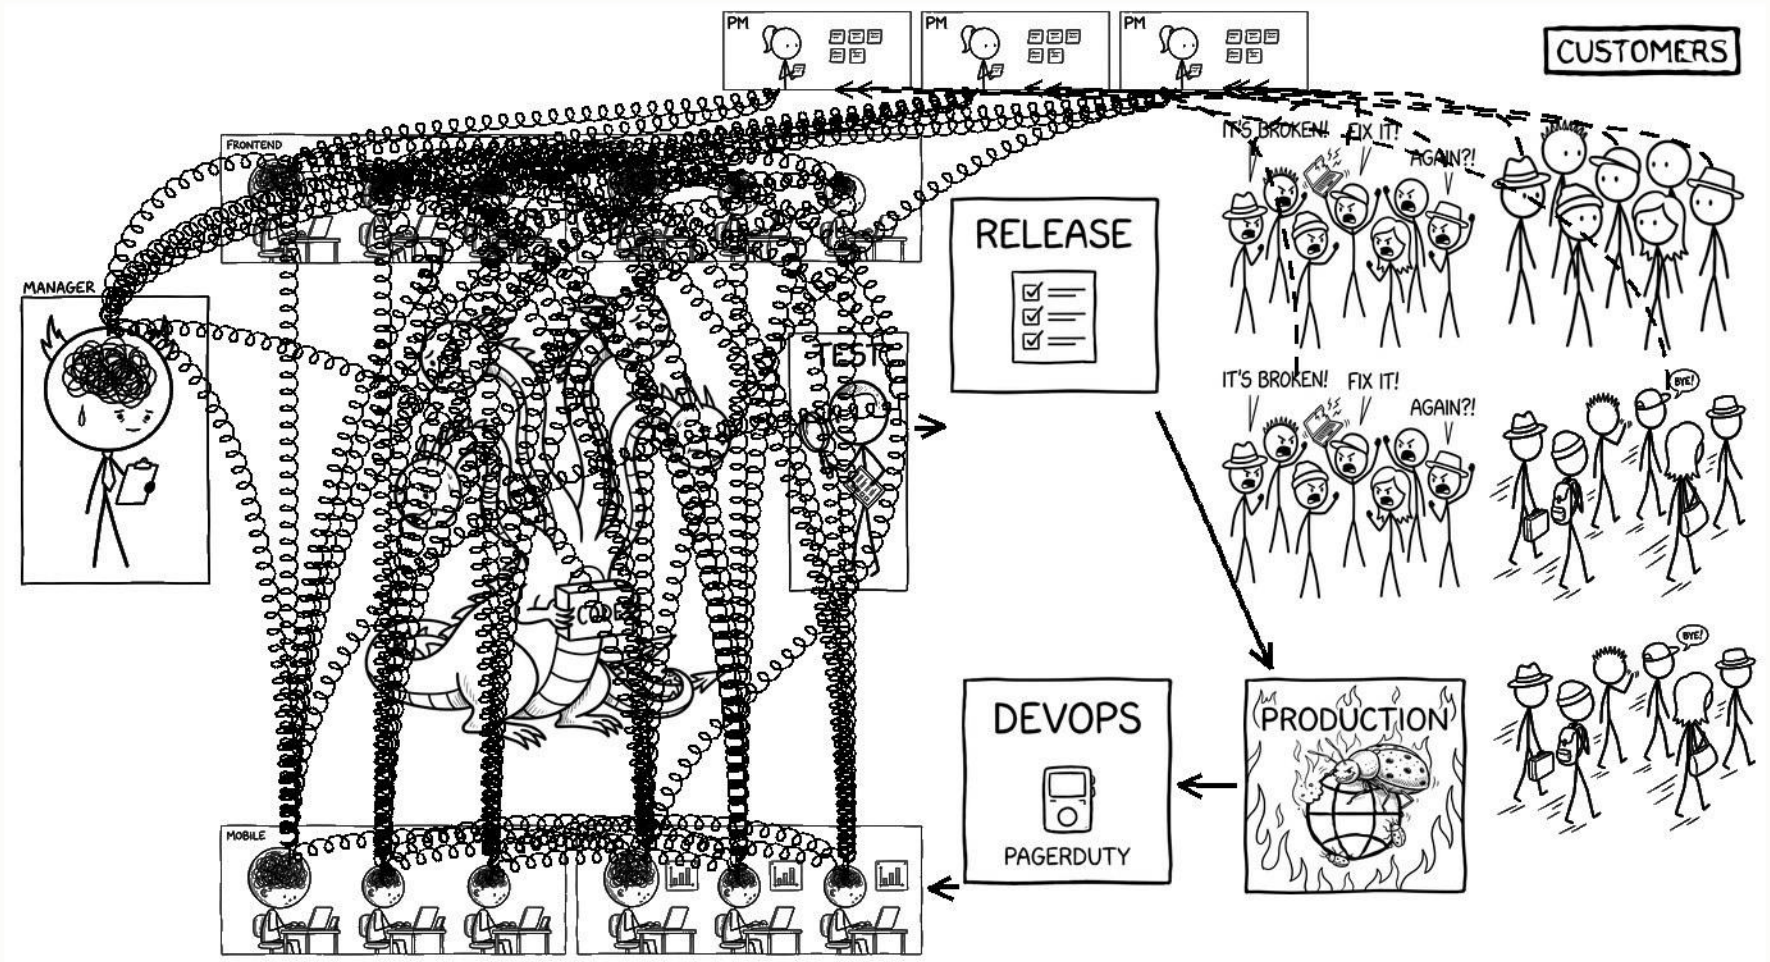

Two teams, and a TL/M in the middle. What changed: the team splits into frontend and backend, and the original engineer becomes the TL/M, in their own box, with a phone to each team; the PM now has one line, to the TL/M. Their brain is bigger than ever, because they're the one who knows how both halves fit together. Each team's heads are busy too. And the code didn't split: the dragon sits between the teams, a head looking each way, and nobody is sure whose it is.

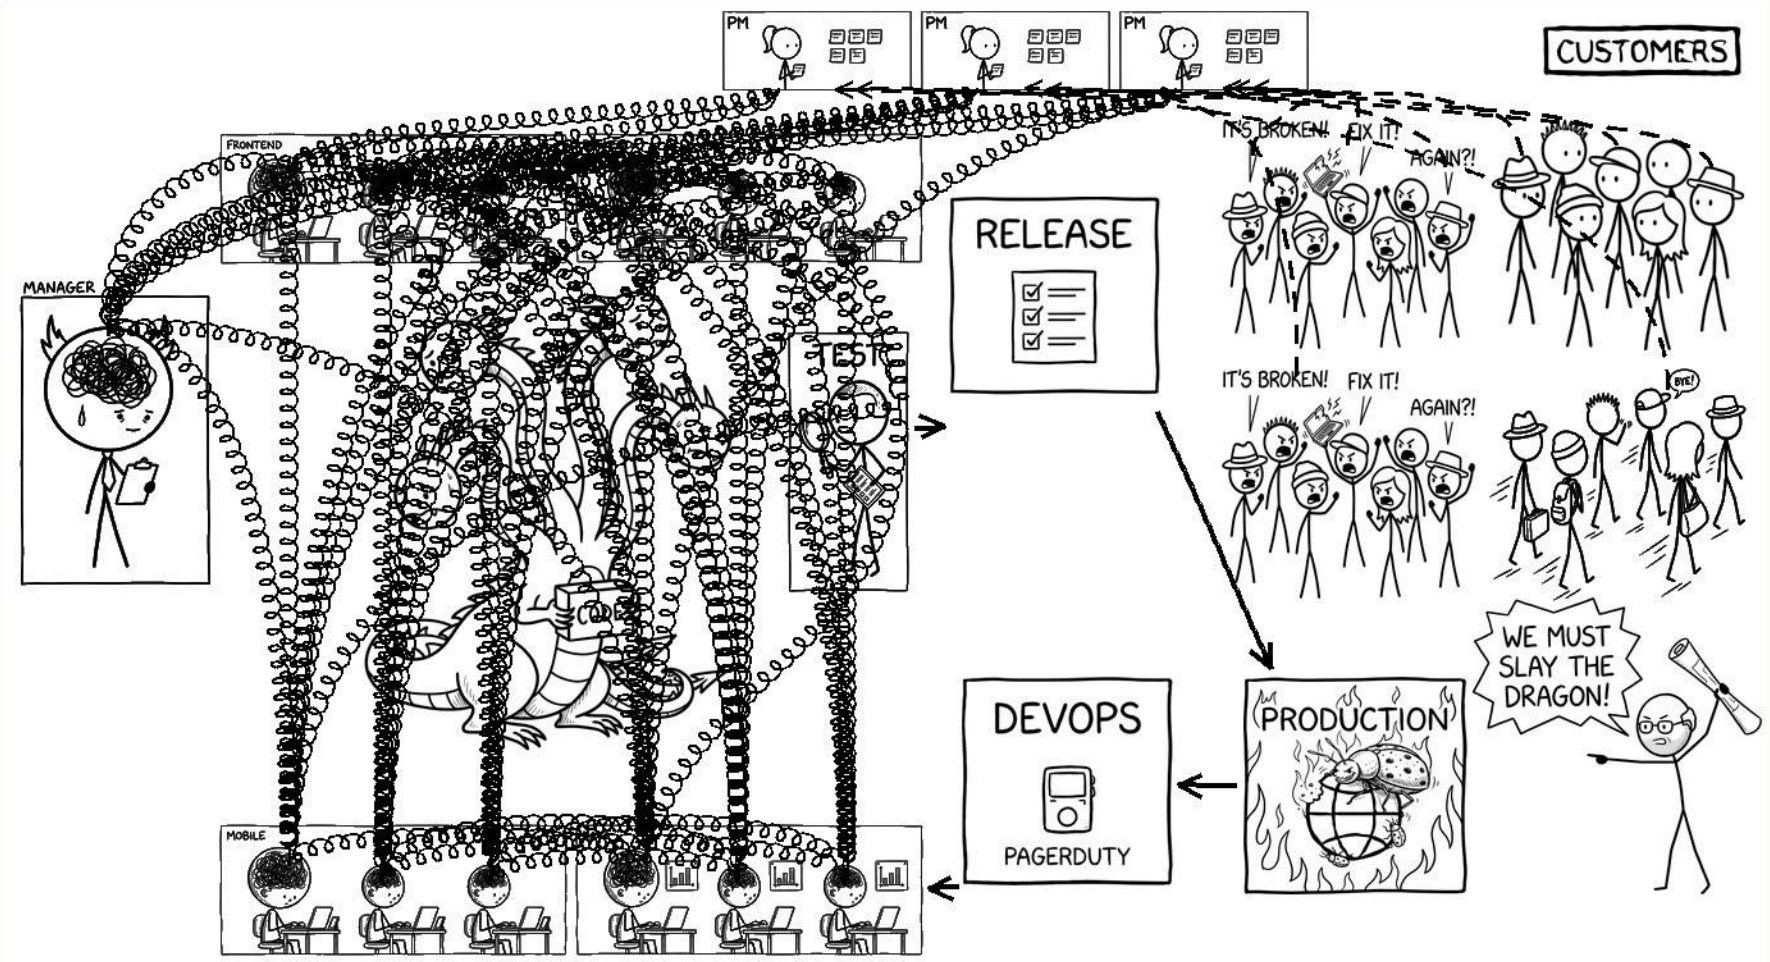

A bug in production. What changed: a bug gets into production. The customers are up in arms and the PM yells: why didn't you catch this? Each team has grown, the dragon has grown more heads and tails, and even the TL/M, the one person who held it all together, admits: "I don't understand it anymore!"

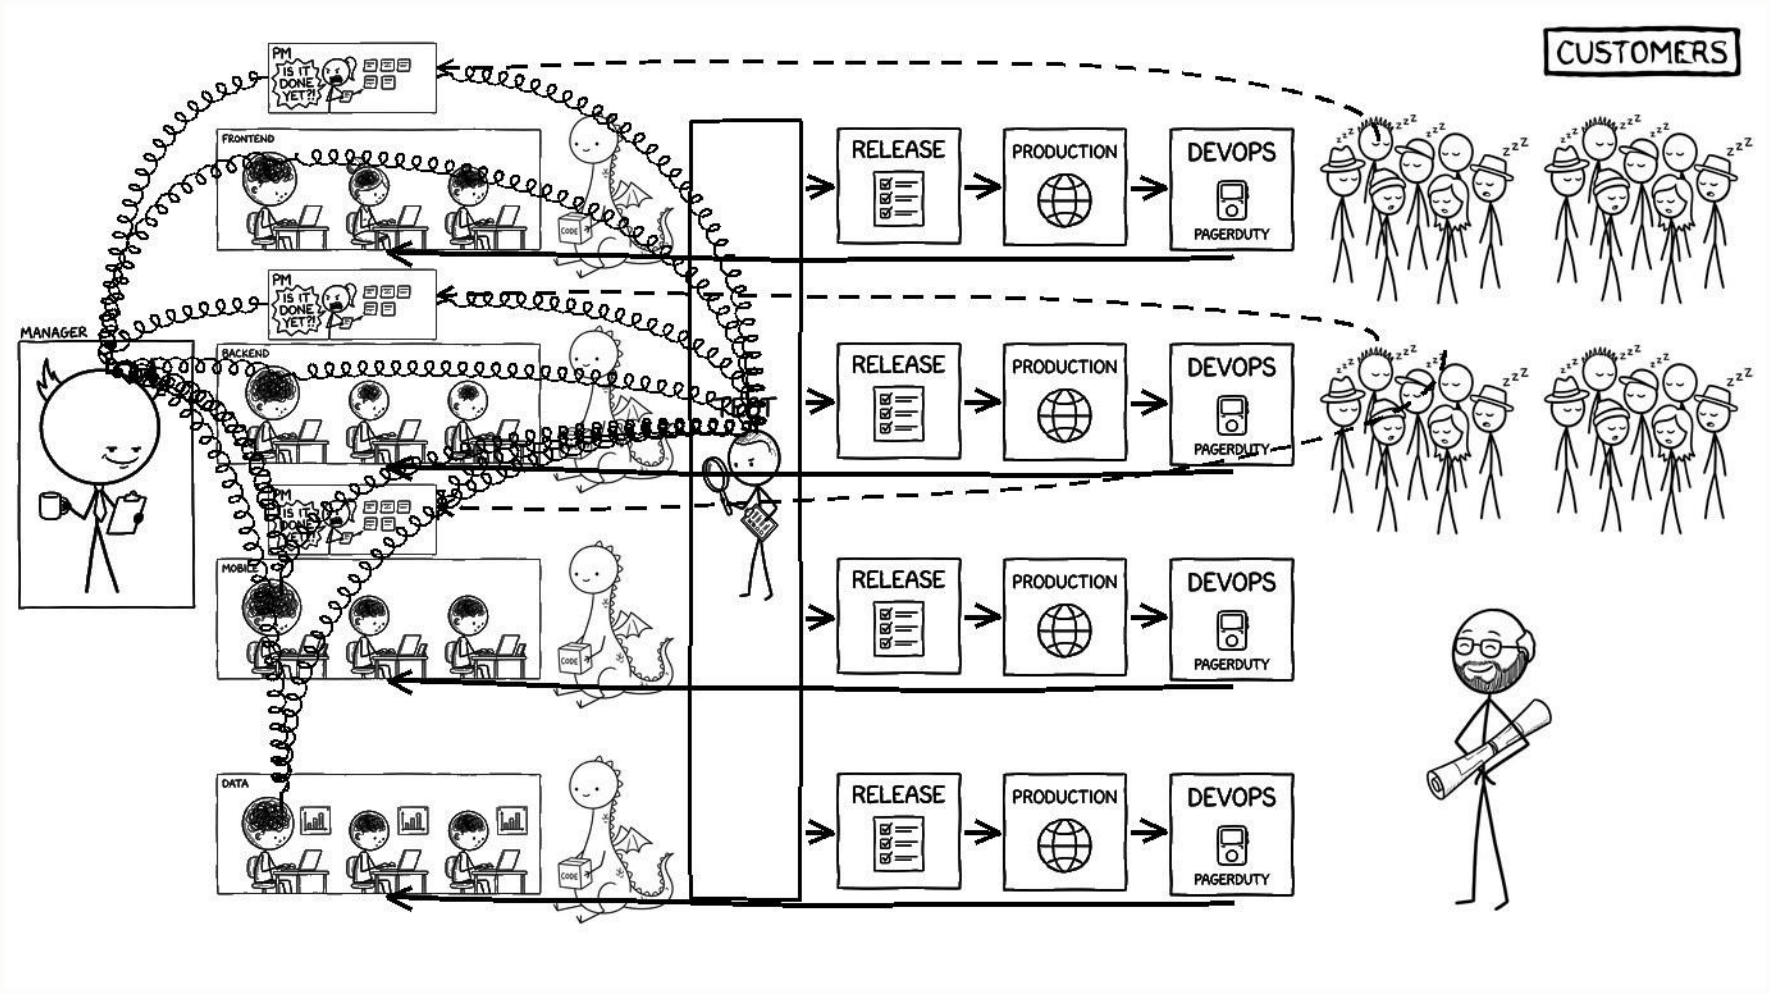

A test step: QA joins. What changed: a TEST box appears right before Release, and QA sits in it. Nothing ships until it passes TEST, and QA has a phone line back to each team to report what they find. The dragon is still huge and complicated, but under the magnifying glass it behaves itself: no more fire.

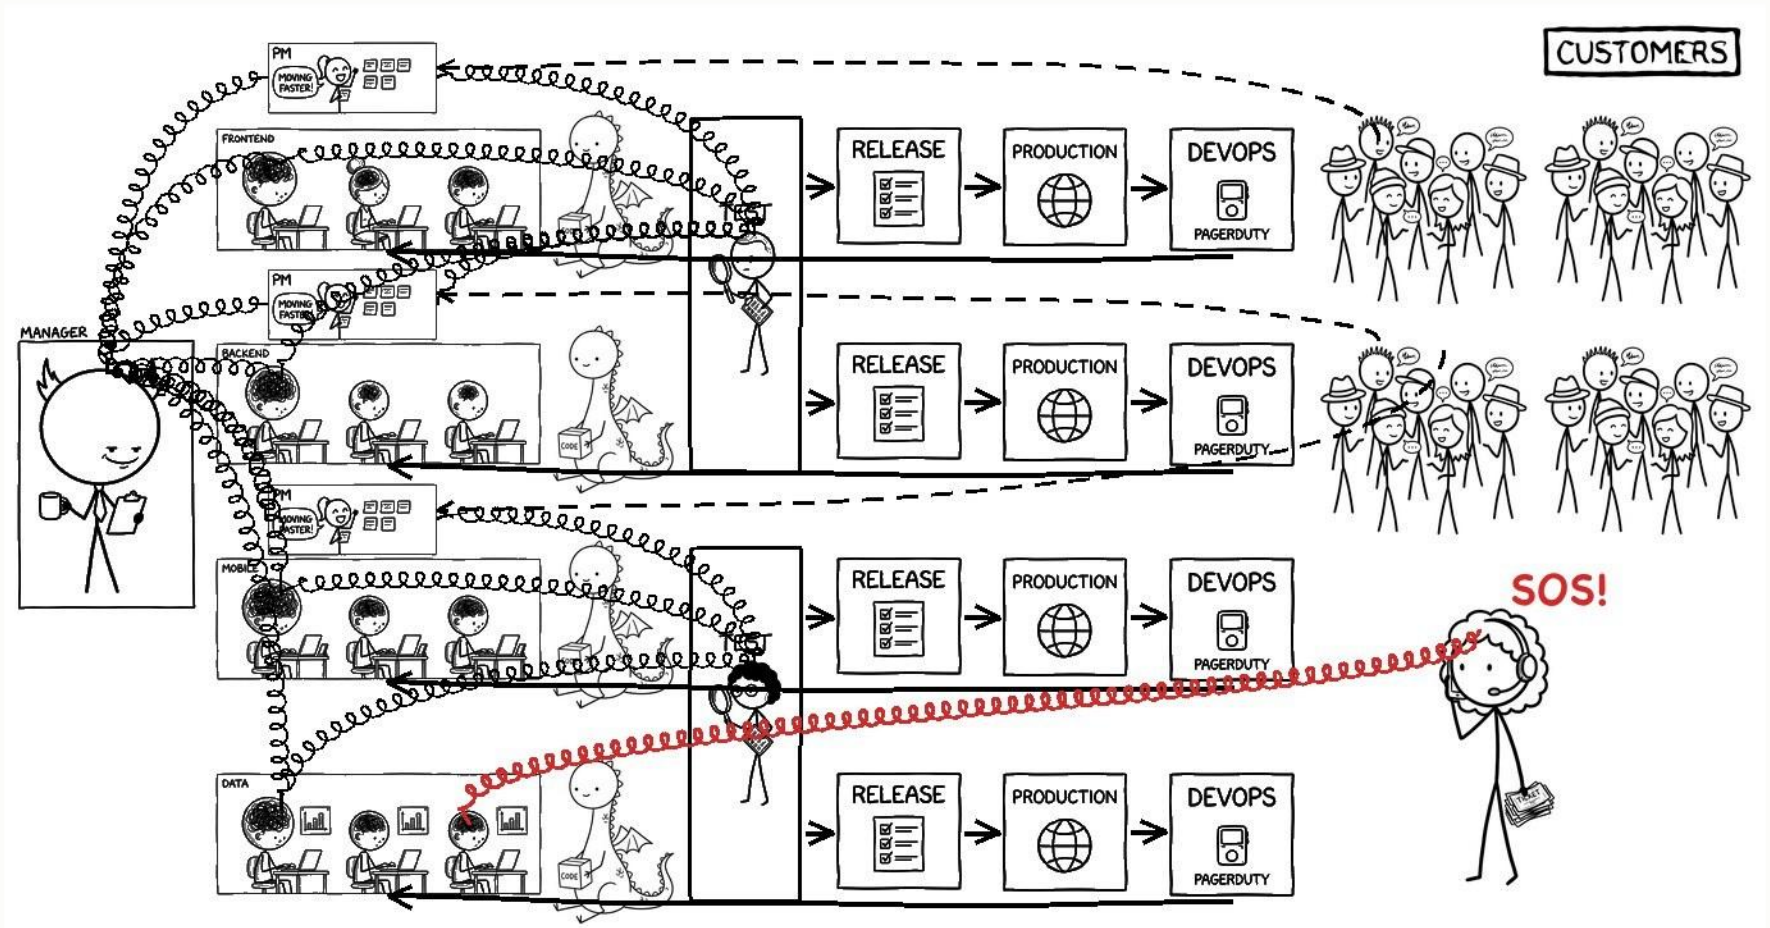

Four teams, three PMs, one manager. What changed: lots more customers, so the PM role grows to three. Engineering is now four smaller teams surrounding the same dragon, and each team has grown its own big-brain engineer. The original big-brain engineer has become a manager. Every team still needs a phone line to every other team, because they all share one dragon: count the cords.

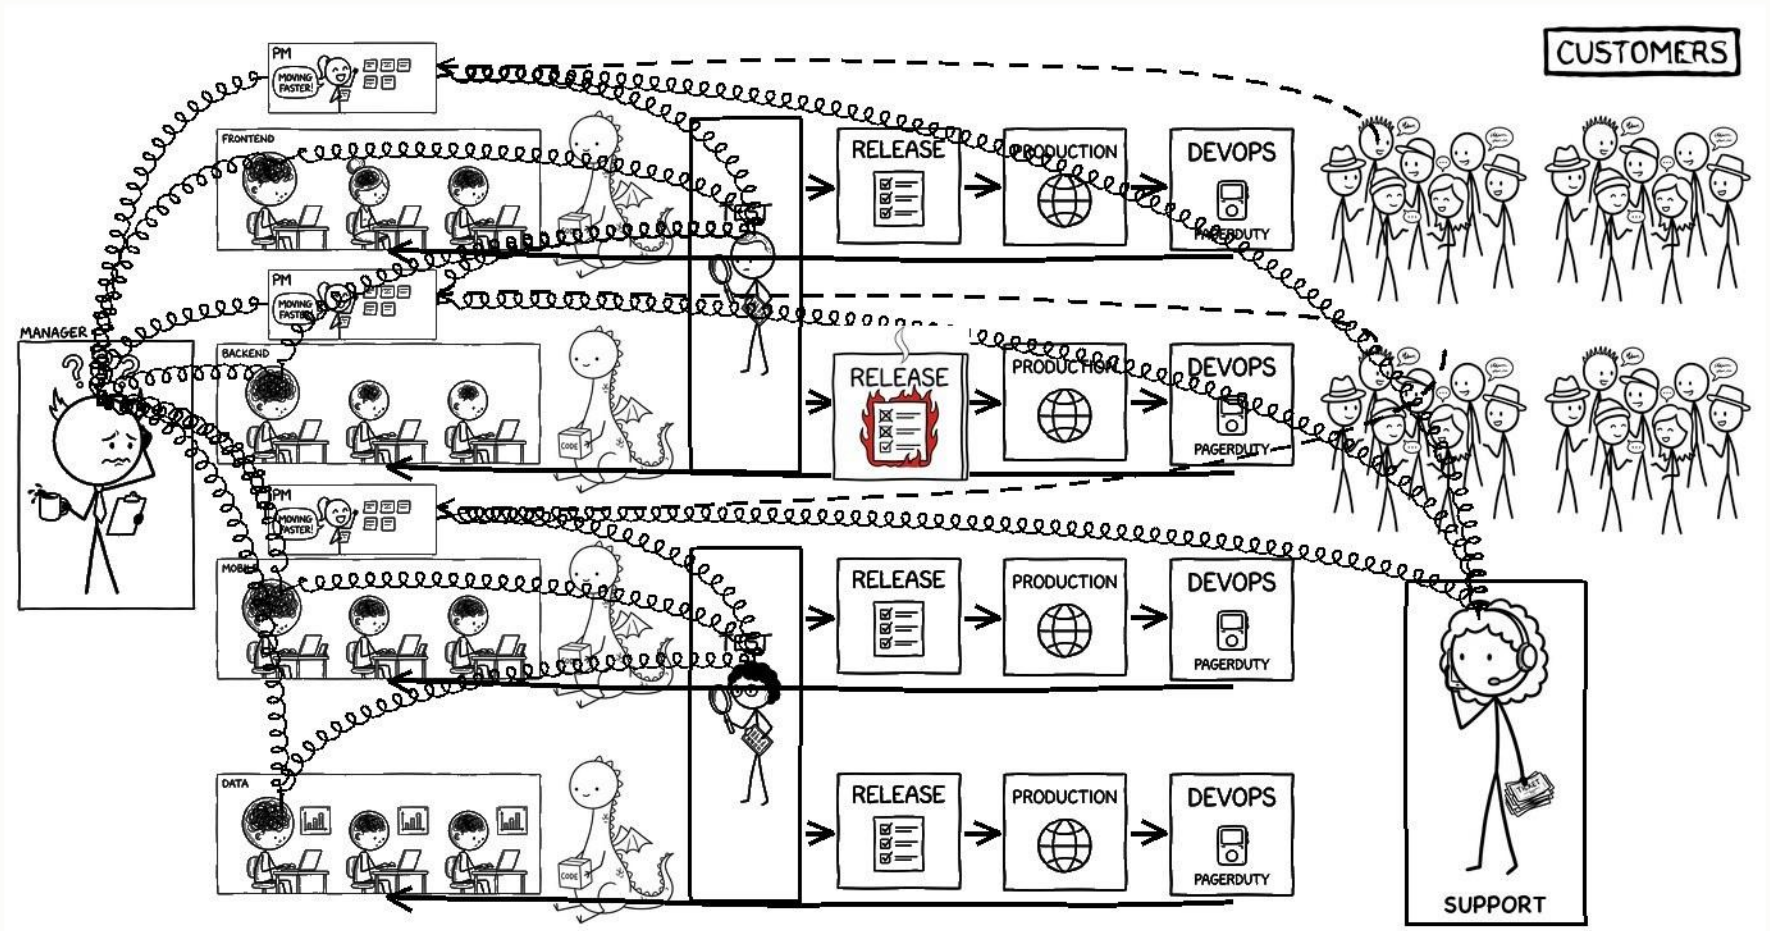

Enter the Architect. Same picture, one new character. The Architect looks at the tangle of phone lines and sees the real problem: everyone has to talk to everyone because they all share one giant dragon. "We must slay the dragon!"

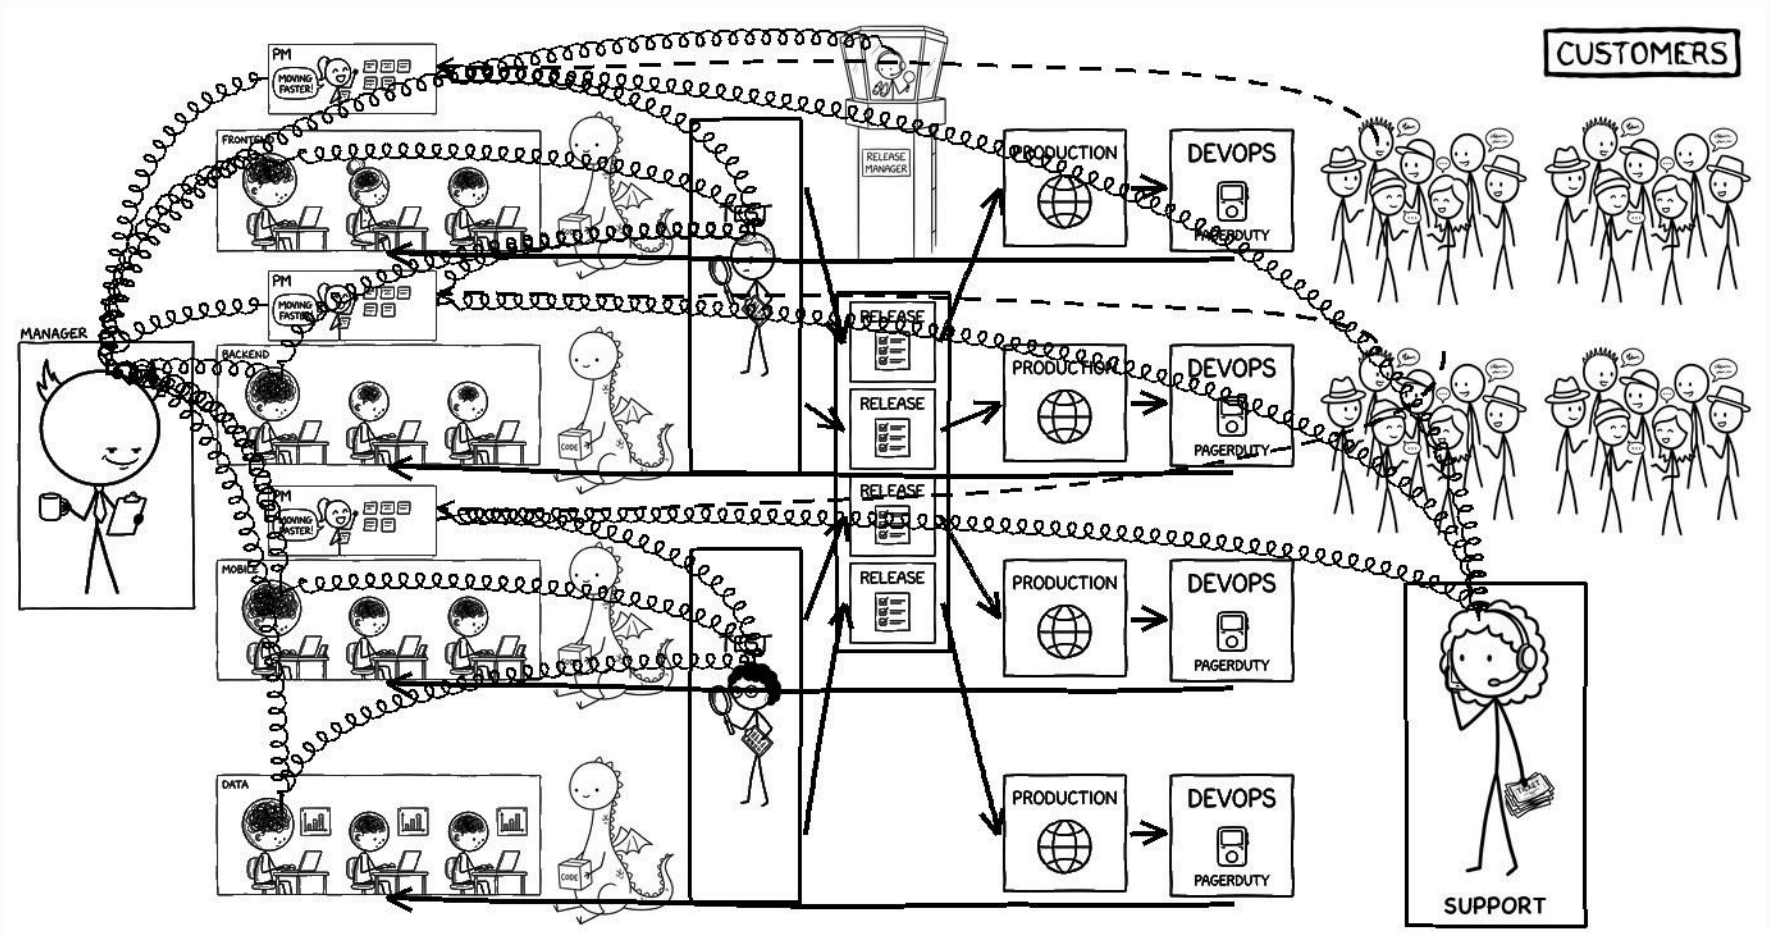

The dragon, slain (four times smaller). What changed: the big dragon is split into four medium dragons, one per team, and each team gets its own Release Production PagerDuty loop. One QA person still tests for everyone. The phone-line mess is gone. The Architect is delighted, and the Manager's brain has shrunk to a classic pointy-haired boss. But the untangling took a long time: the customers fell asleep, and the PMs are shouting "Is it done yet?!"

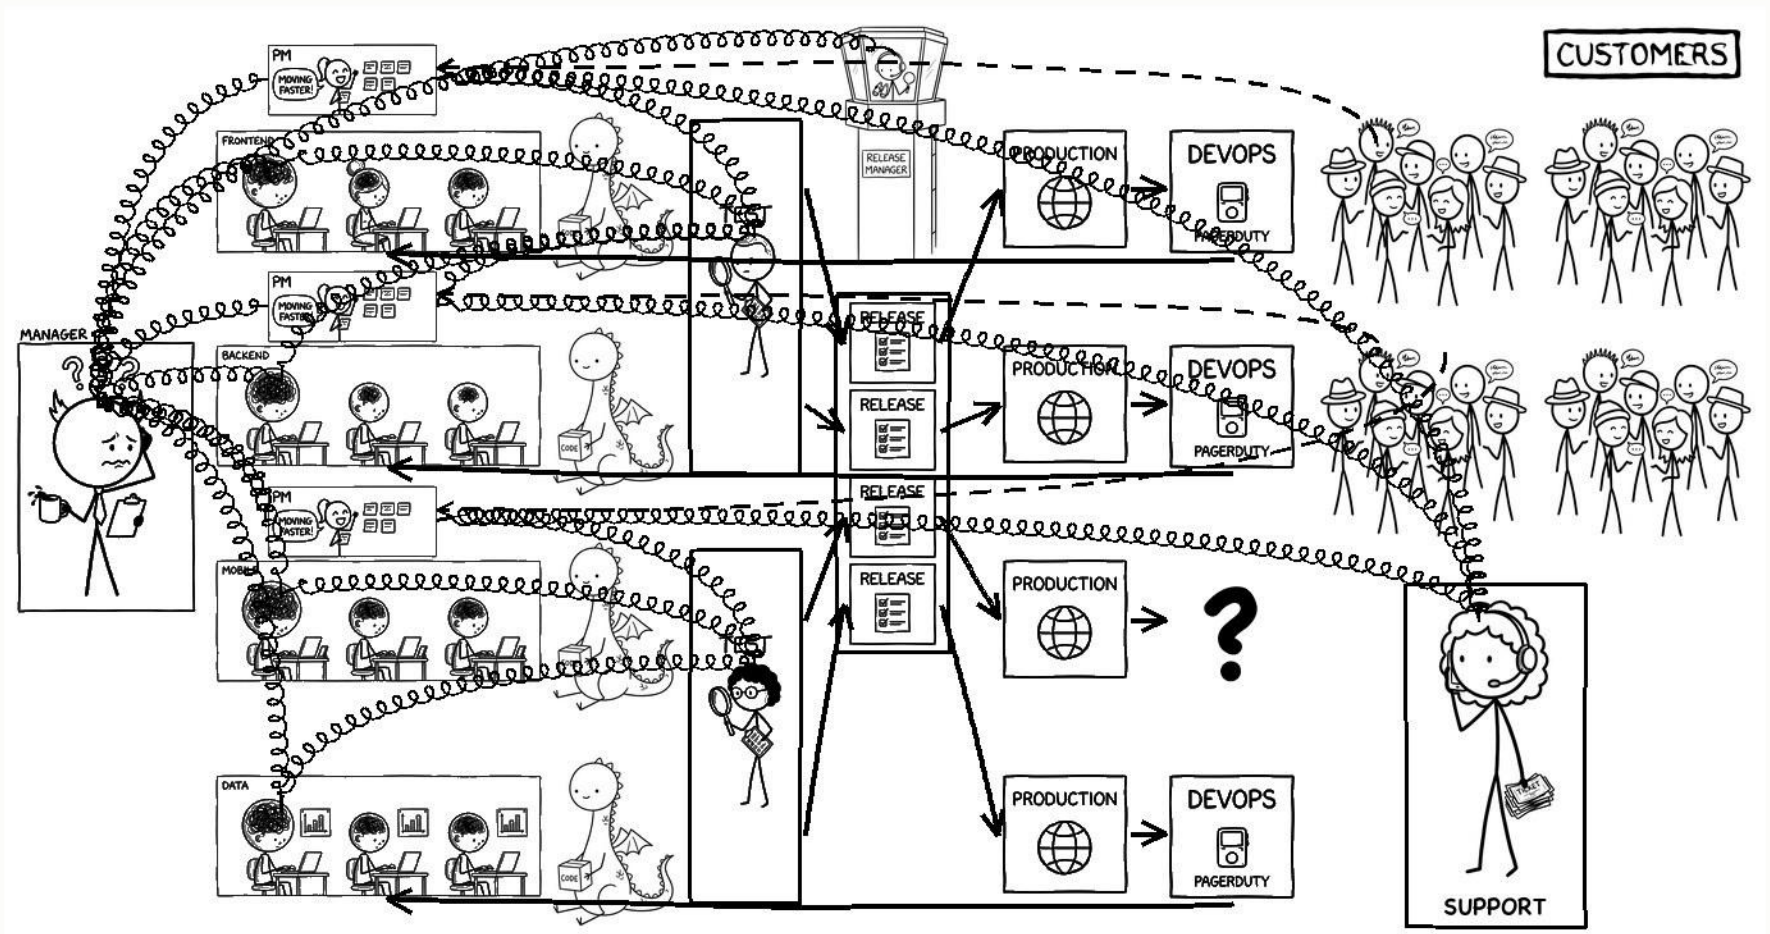

QA splits, Support arrives. What changed: one QA person can't keep up with four teams, so QA splits in two, each with phone lines back to the PMs and the team leads they cover. Customer Support shows up too, with one red emergency line: "SOS!" straight to an engineer, not a lead. Support can break through the system when it matters. It works: the customers are awake and chattering again, and the PMs are happy: "Moving faster!"

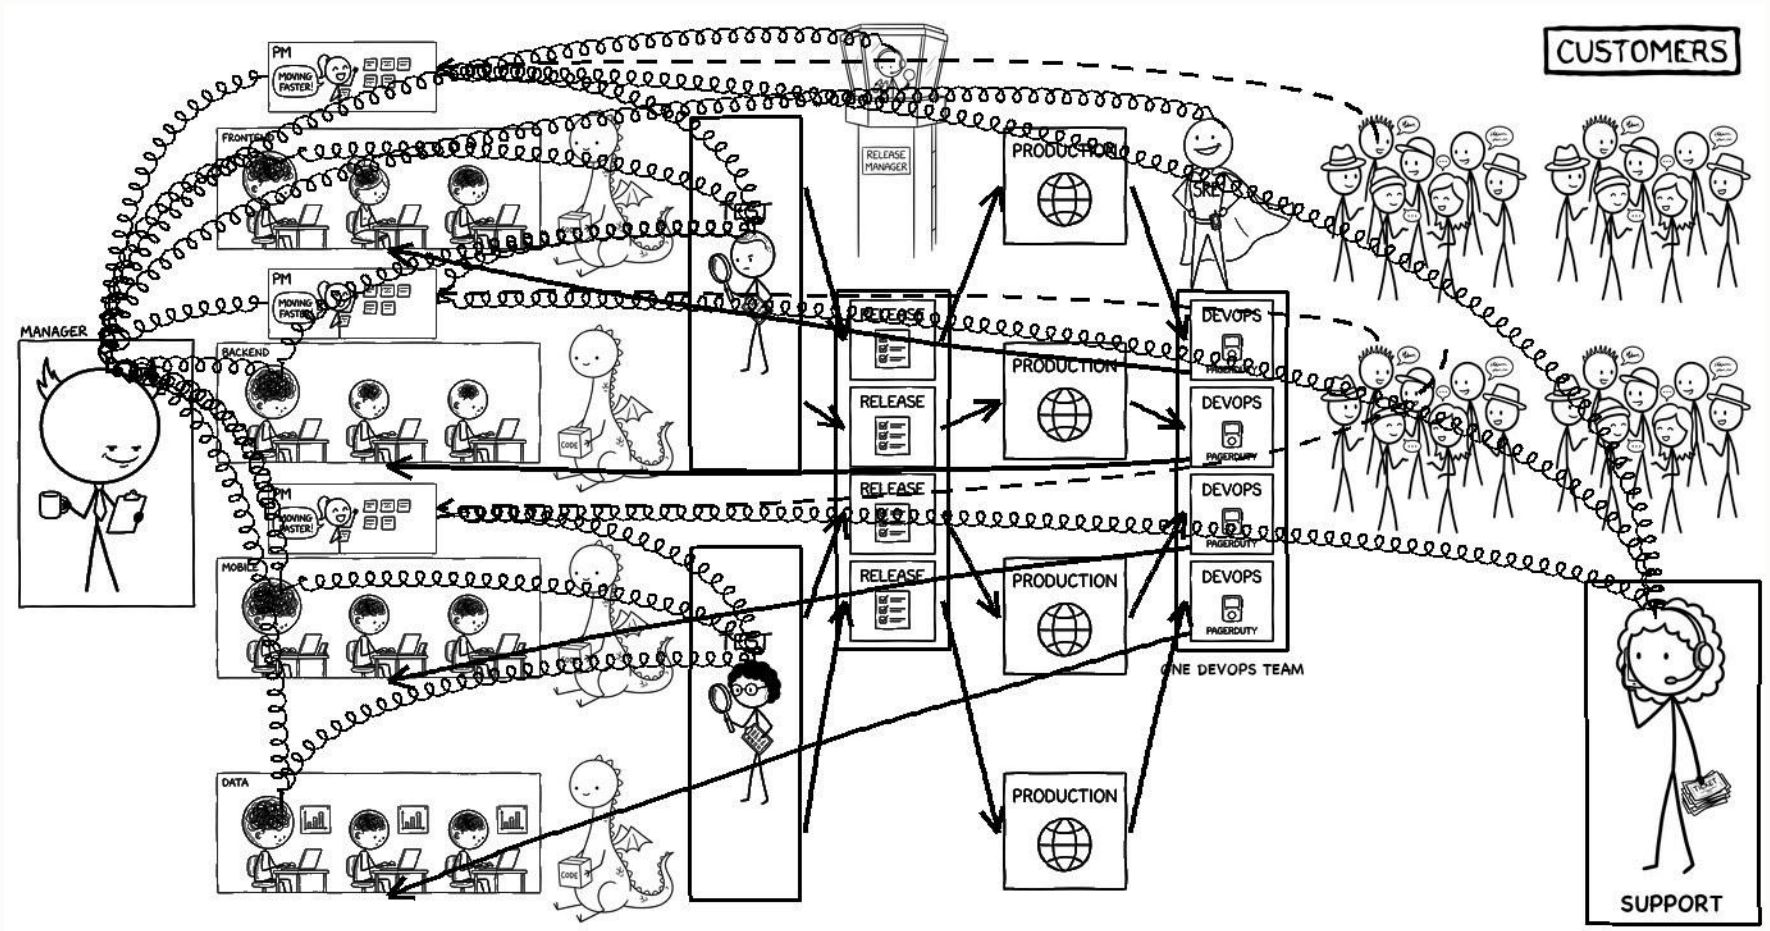

A release catches fire. What changed: one team's release goes up in flames. Four teams are each shipping on their own schedule, through their own release, and nobody is looking at all of them together. The Manager has no idea what happened. Support now sits in its own box, with a line to every PM.

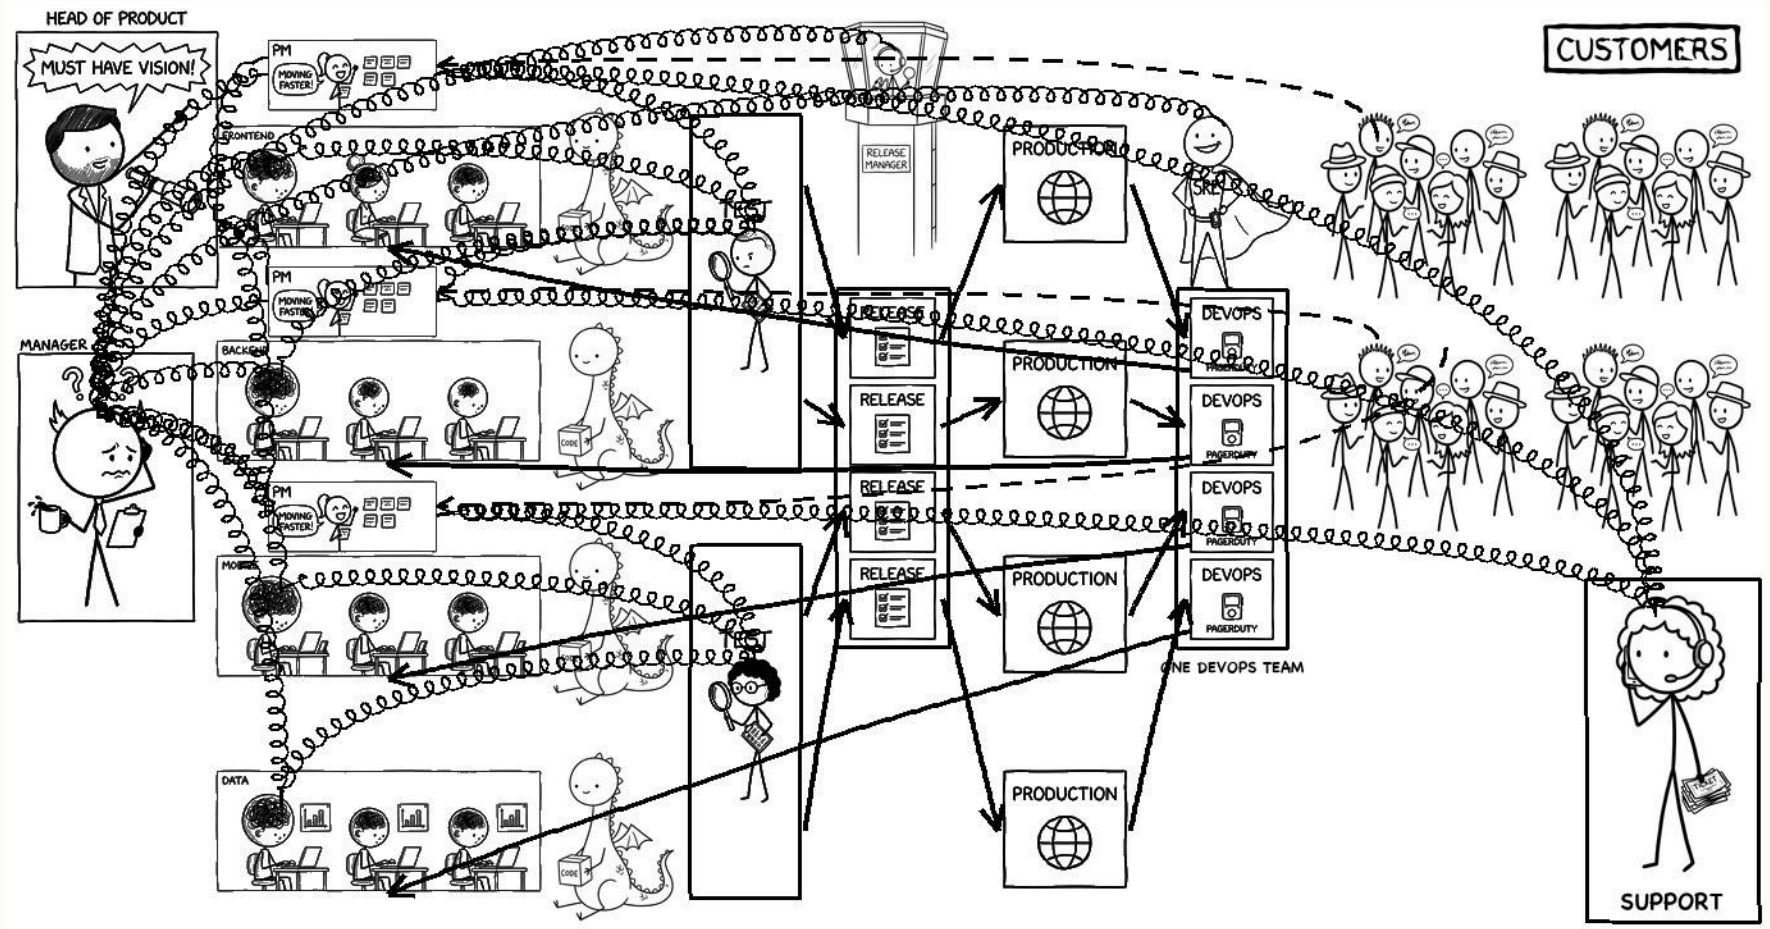

Air traffic control for releases. What changed: the four releases are grouped together, and a Release Manager watches over all of them like air traffic control, deciding what lands when. No more surprise fires, and the Manager is happy again.

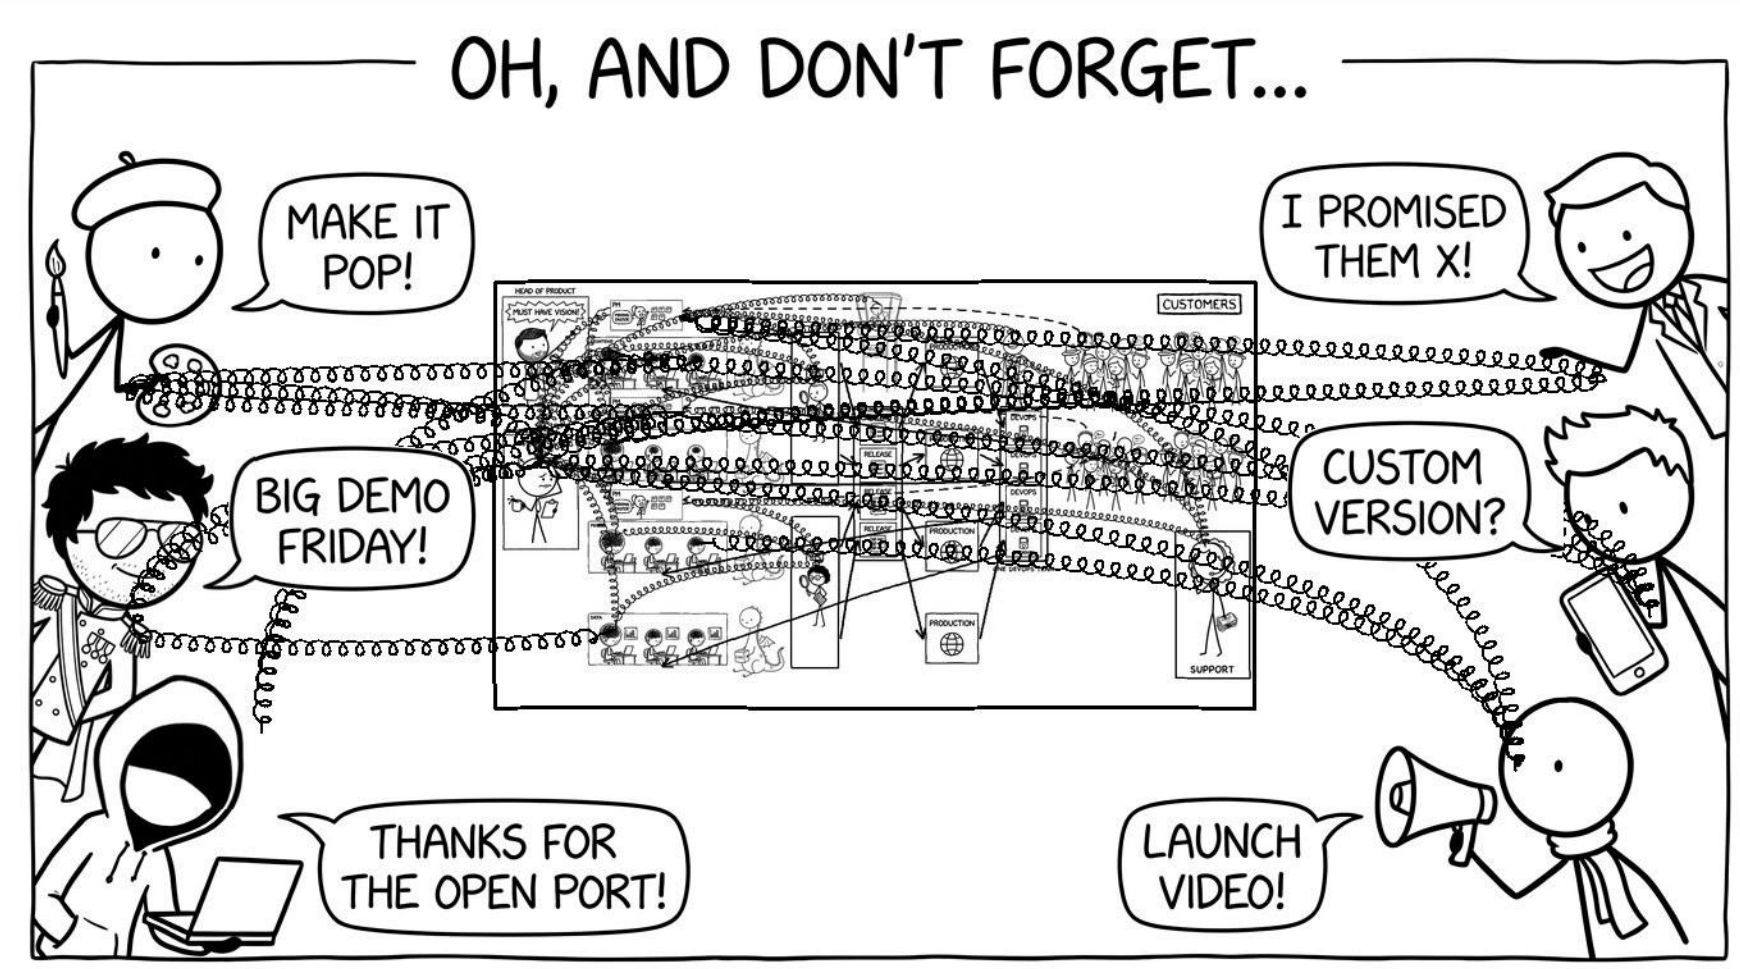

Who's on call? What changed: one team's DevOps / PagerDuty quietly disappears. Maybe the person left, maybe the rotation lapsed. Production still runs, but when it breaks, nobody gets paged.
The Manager is confused again.

Enter the SRE. What changed: the DevOps work is pulled together into one team that covers every product, so nothing falls through the cracks. And a new hero shows up: the SRE, whose job is keeping production reliable across all of them.

Head of Product. What changed: with three PMs pulling in different directions, a Head of Product appears above them all, with a line to every PM: "Must have vision!" The Manager, who now has to square that vision with four teams, a Release Manager and an SRE, is confused again.

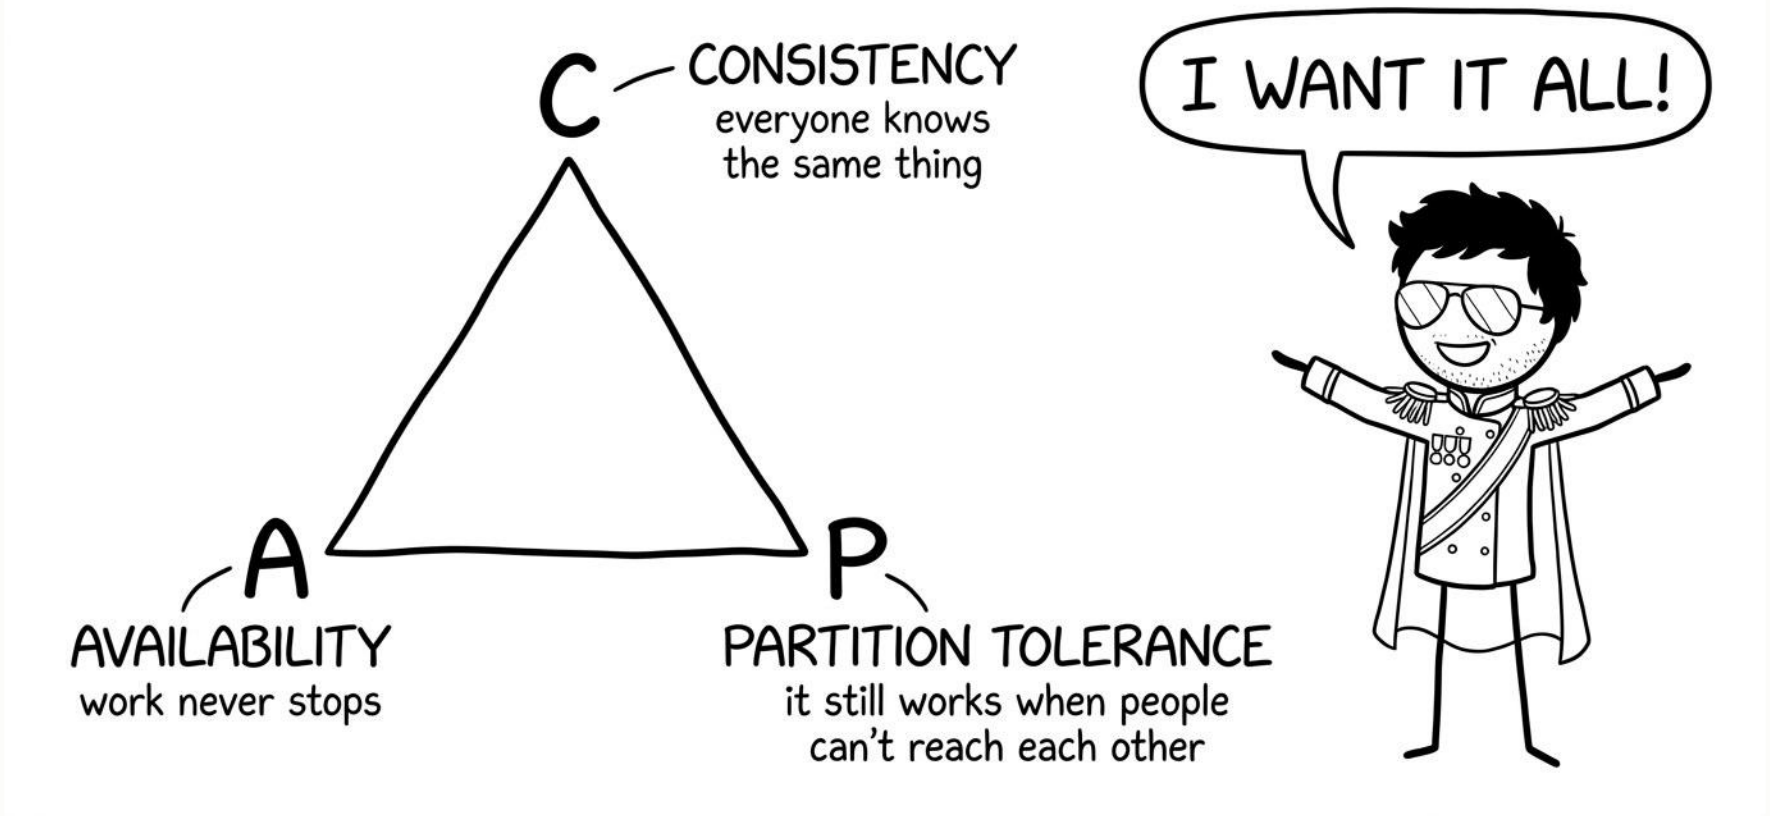

Oh, and don't forget... Zoom out, and the org chart was never the whole story. Design, the CEO, two Sales people and Marketing all want something, and a hacker has found the open port. None of them go through the structure: each one rings the Manager, a PM and whichever engineer picks up.

PART 2

Why It's So Hard

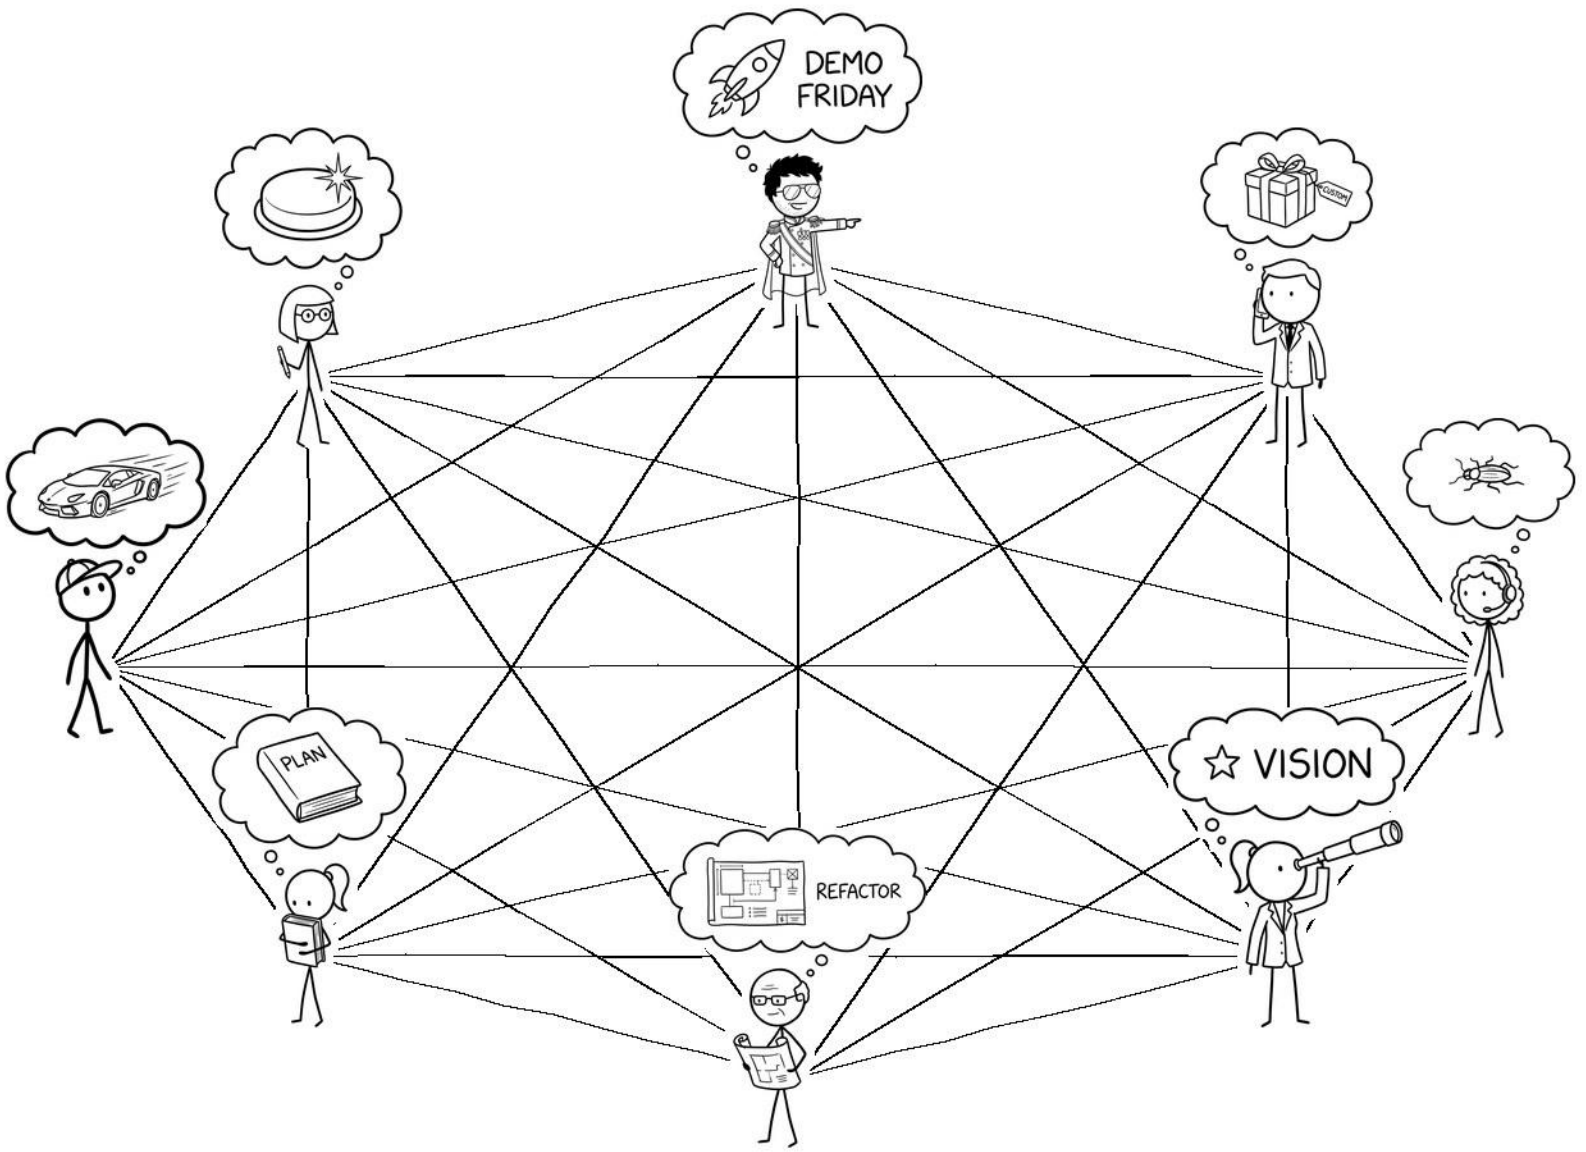

Everyone's signal is different, and that can't be avoided

Part 2: Why It's So Hard. That's how the org grows. Questions so far? Next: why, even with good people at every step, what gets built is never quite what everyone wanted.

The CAP theorem. There's a famous result in computer science for any system spread across many places. You want three things: everyone has the same information, work never stops, and it keeps working when parts can't reach each other. Every CEO wants all three. Let's look at what each one costs.

CONSISTENCY: everyone knows the same thing

Every line is a conversation that has to happen.

2 people = 1 line

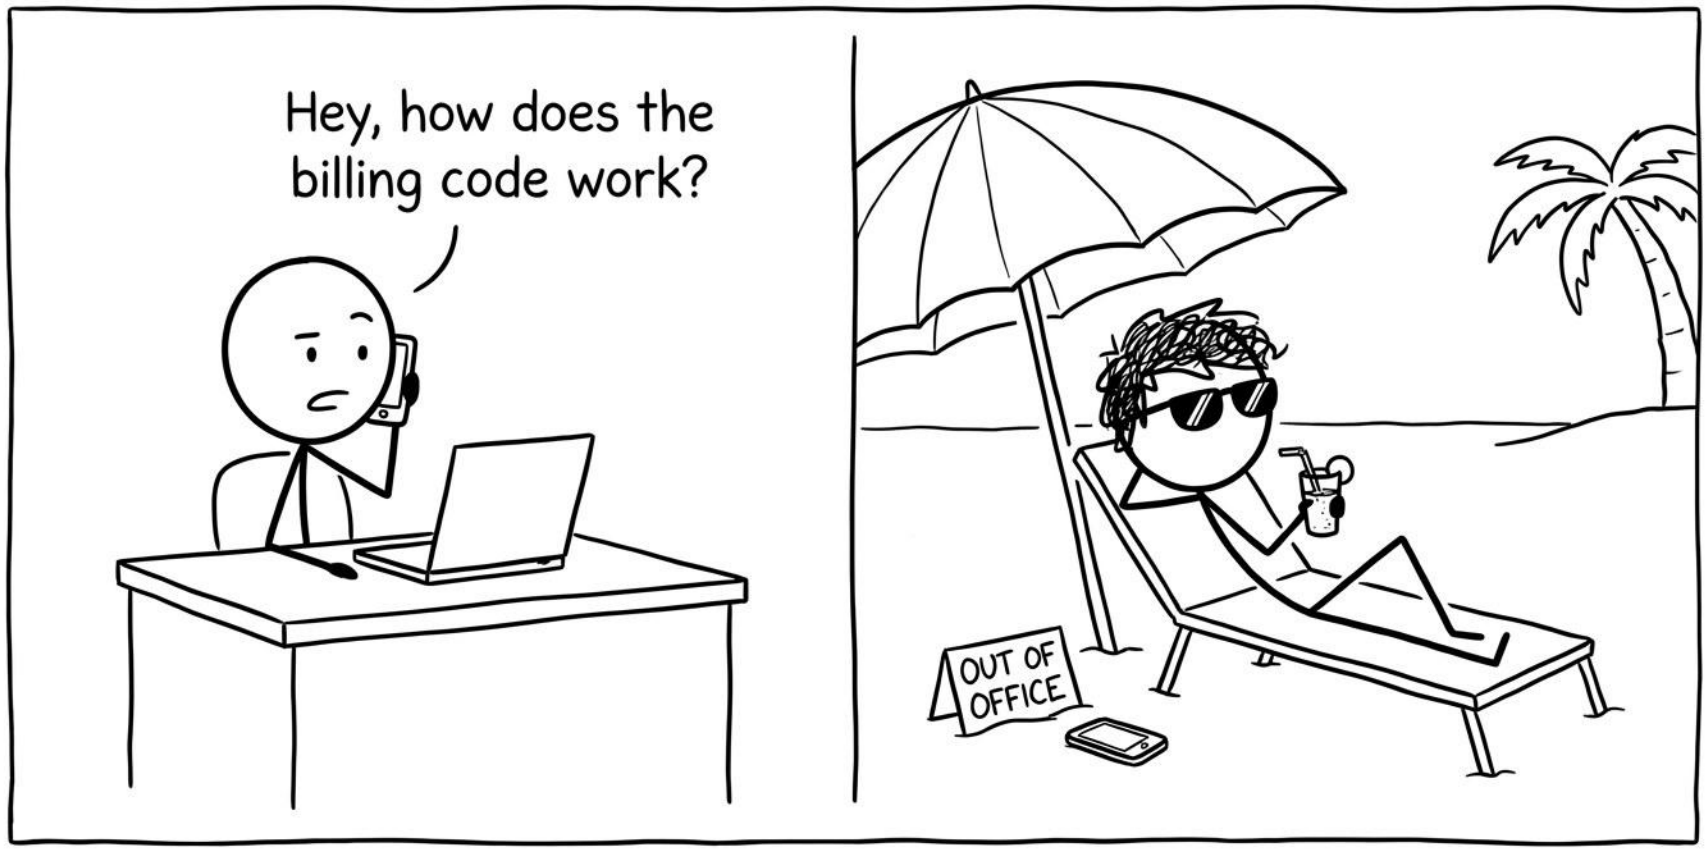

4 people = 6 lines

8 people = 28 lines

50 people = 1,225 lines

...and they all want something different.

Consistency: everyone knows the same thing. For everyone to know the same thing, every pair of people has to stay in sync. Eight people is 28 conversations, fifty is over twelve hundred, and every one of these people wants something different. Keeping everyone consistent gets more expensive with every person you add, and it's never finished.

Partition: on vacation. A partition is when people can't reach each other. The simplest one: someone is on vacation, and what they know is on the beach with them. And they should be: we want people to take PTO.

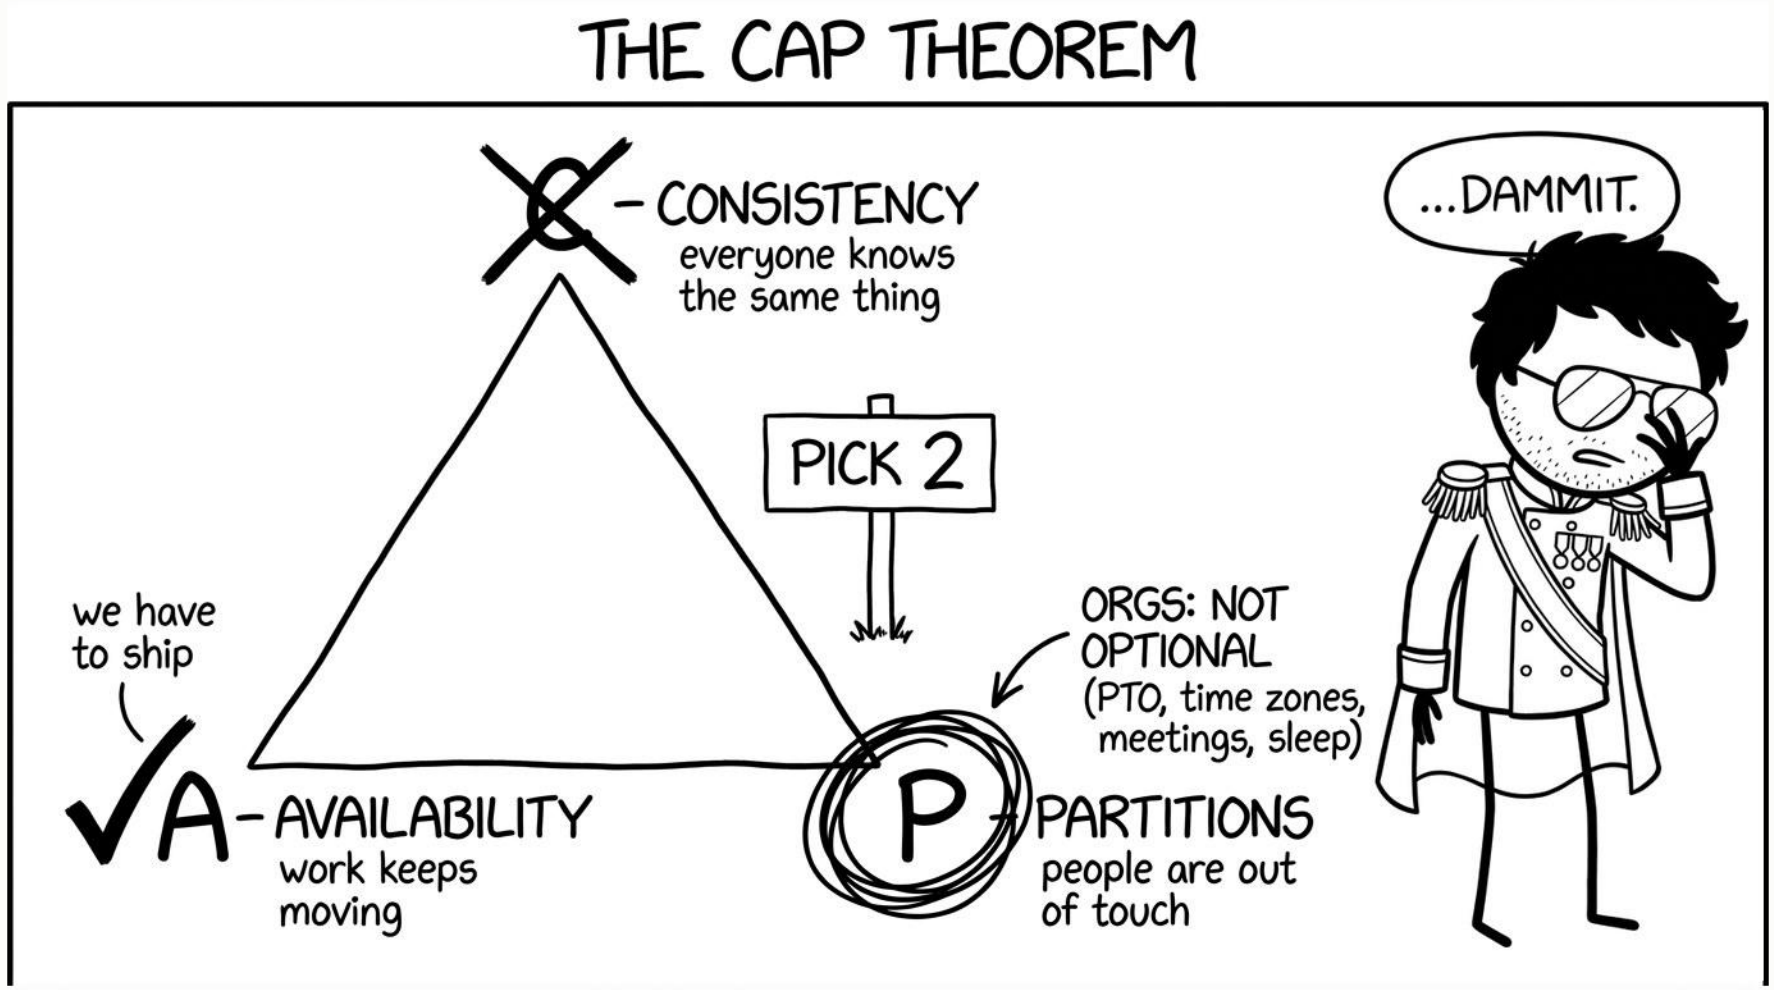

Partition: gone for good. Sometimes the partition is permanent. Someone quits, and everything they knew that wasn't written down leaves with them.

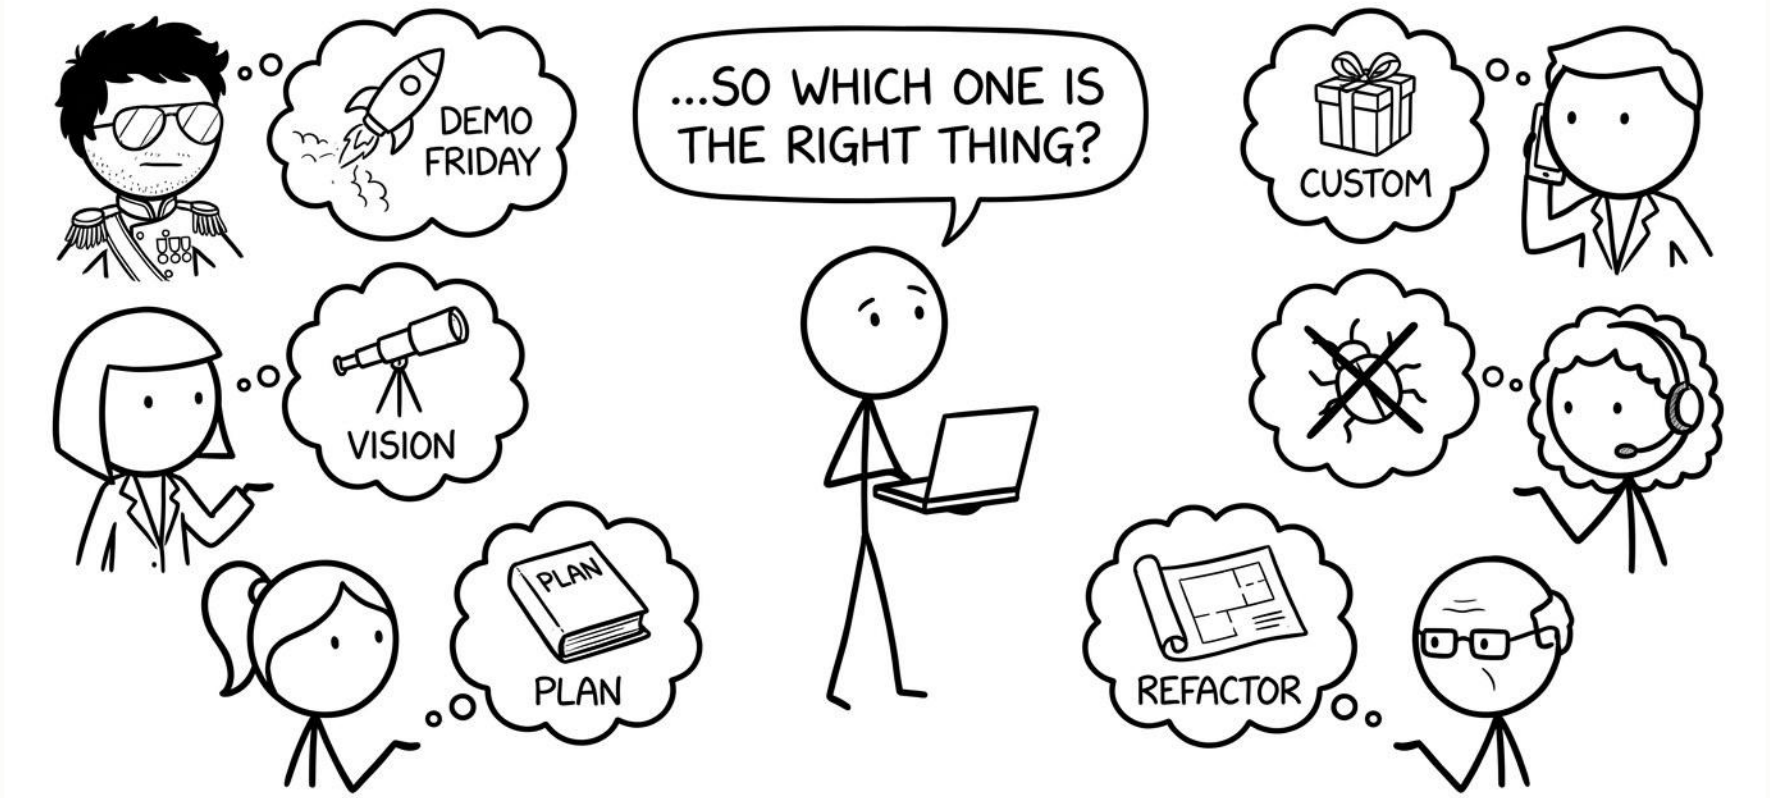

Partition: just busy. Most of the time it's not vacation or quitting. People are just busy. The PM needs an answer from Sales, Sales is with a customer, and the engineer needs to pick A or B today. In an org, partitions aren't the exception. They're the normal state.

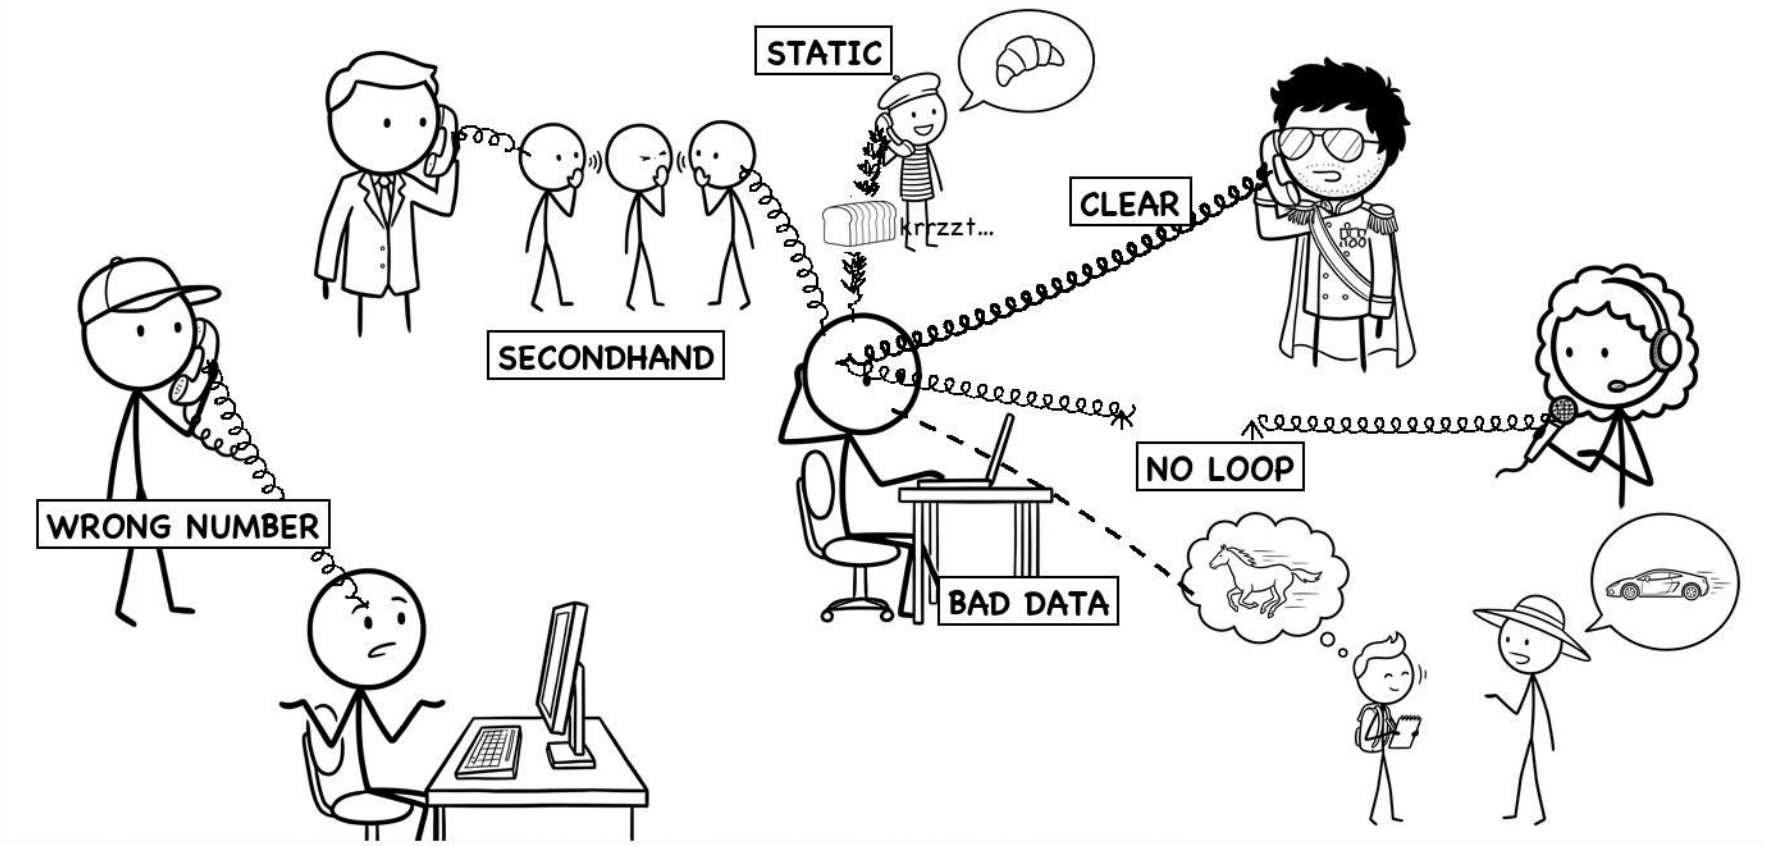

Availability: work never stops... right? Availability means work never stops. But if you insist on consistency, everyone in sync before anything moves, then every partition stops the work. Somebody is always out, so nothing ever ships.

The CAP theorem. Turns out, there is a famous computer science proof showing this is unavoidable. You can't just hire better people. It's called the CAP theorem, and it says you can only have 2 out of these 3 things. AND: organizations MUST have partitions, so our choice is between Availability and Consistency. Obviously, we choose availability. So we can never have consistency. Dammit.

Everyone has a different "right thing". Everyone has a different view of what is important, and what should be built when. None of them are wrong: each one is looking at a real problem from where they sit. The engineer is the one who has to turn all of it into a single thing to build.

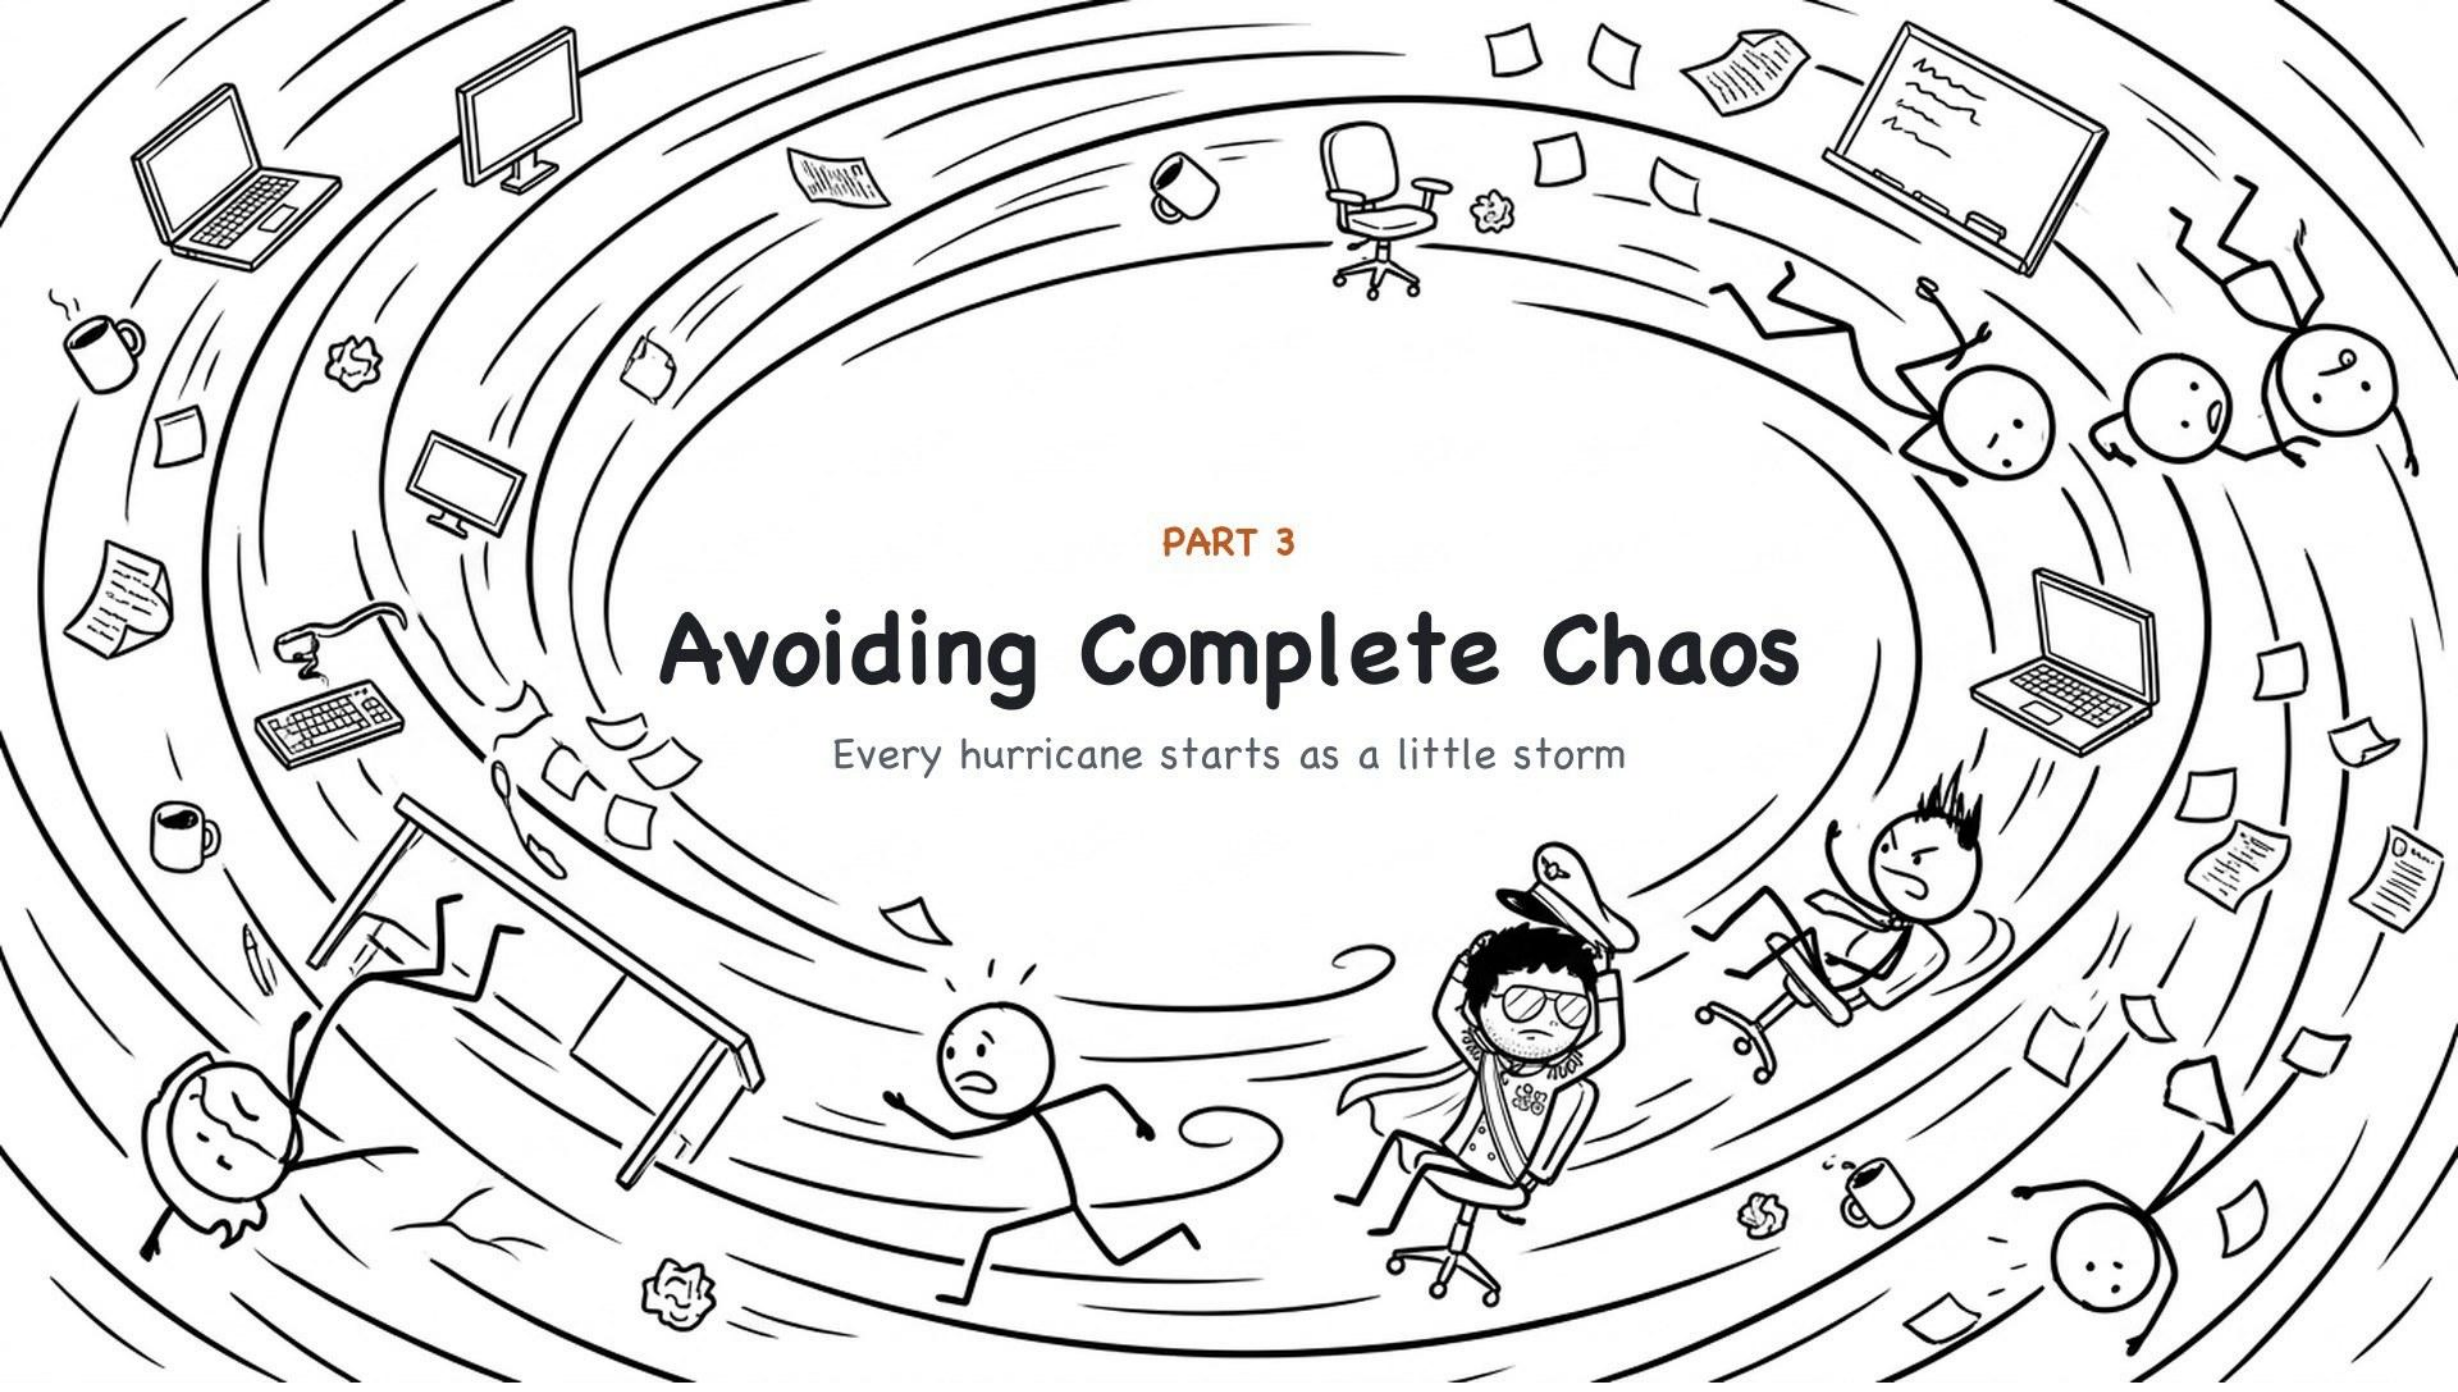

...and every signal arrives differently. And each of those signals reaches each engineer at a different level of clarity. Sometimes the feedback loop doesn't exist at all. Sometimes it goes to the wrong people. Sometimes the data coming in is wrong and can't be trusted.

And that's why we never build "the right thing".

...and that's why. Whatever ships, somebody's signal got lost on the way. That's the title of this talk. And it's not because anyone is bad at their job. Questions before we look at how it goes wrong?

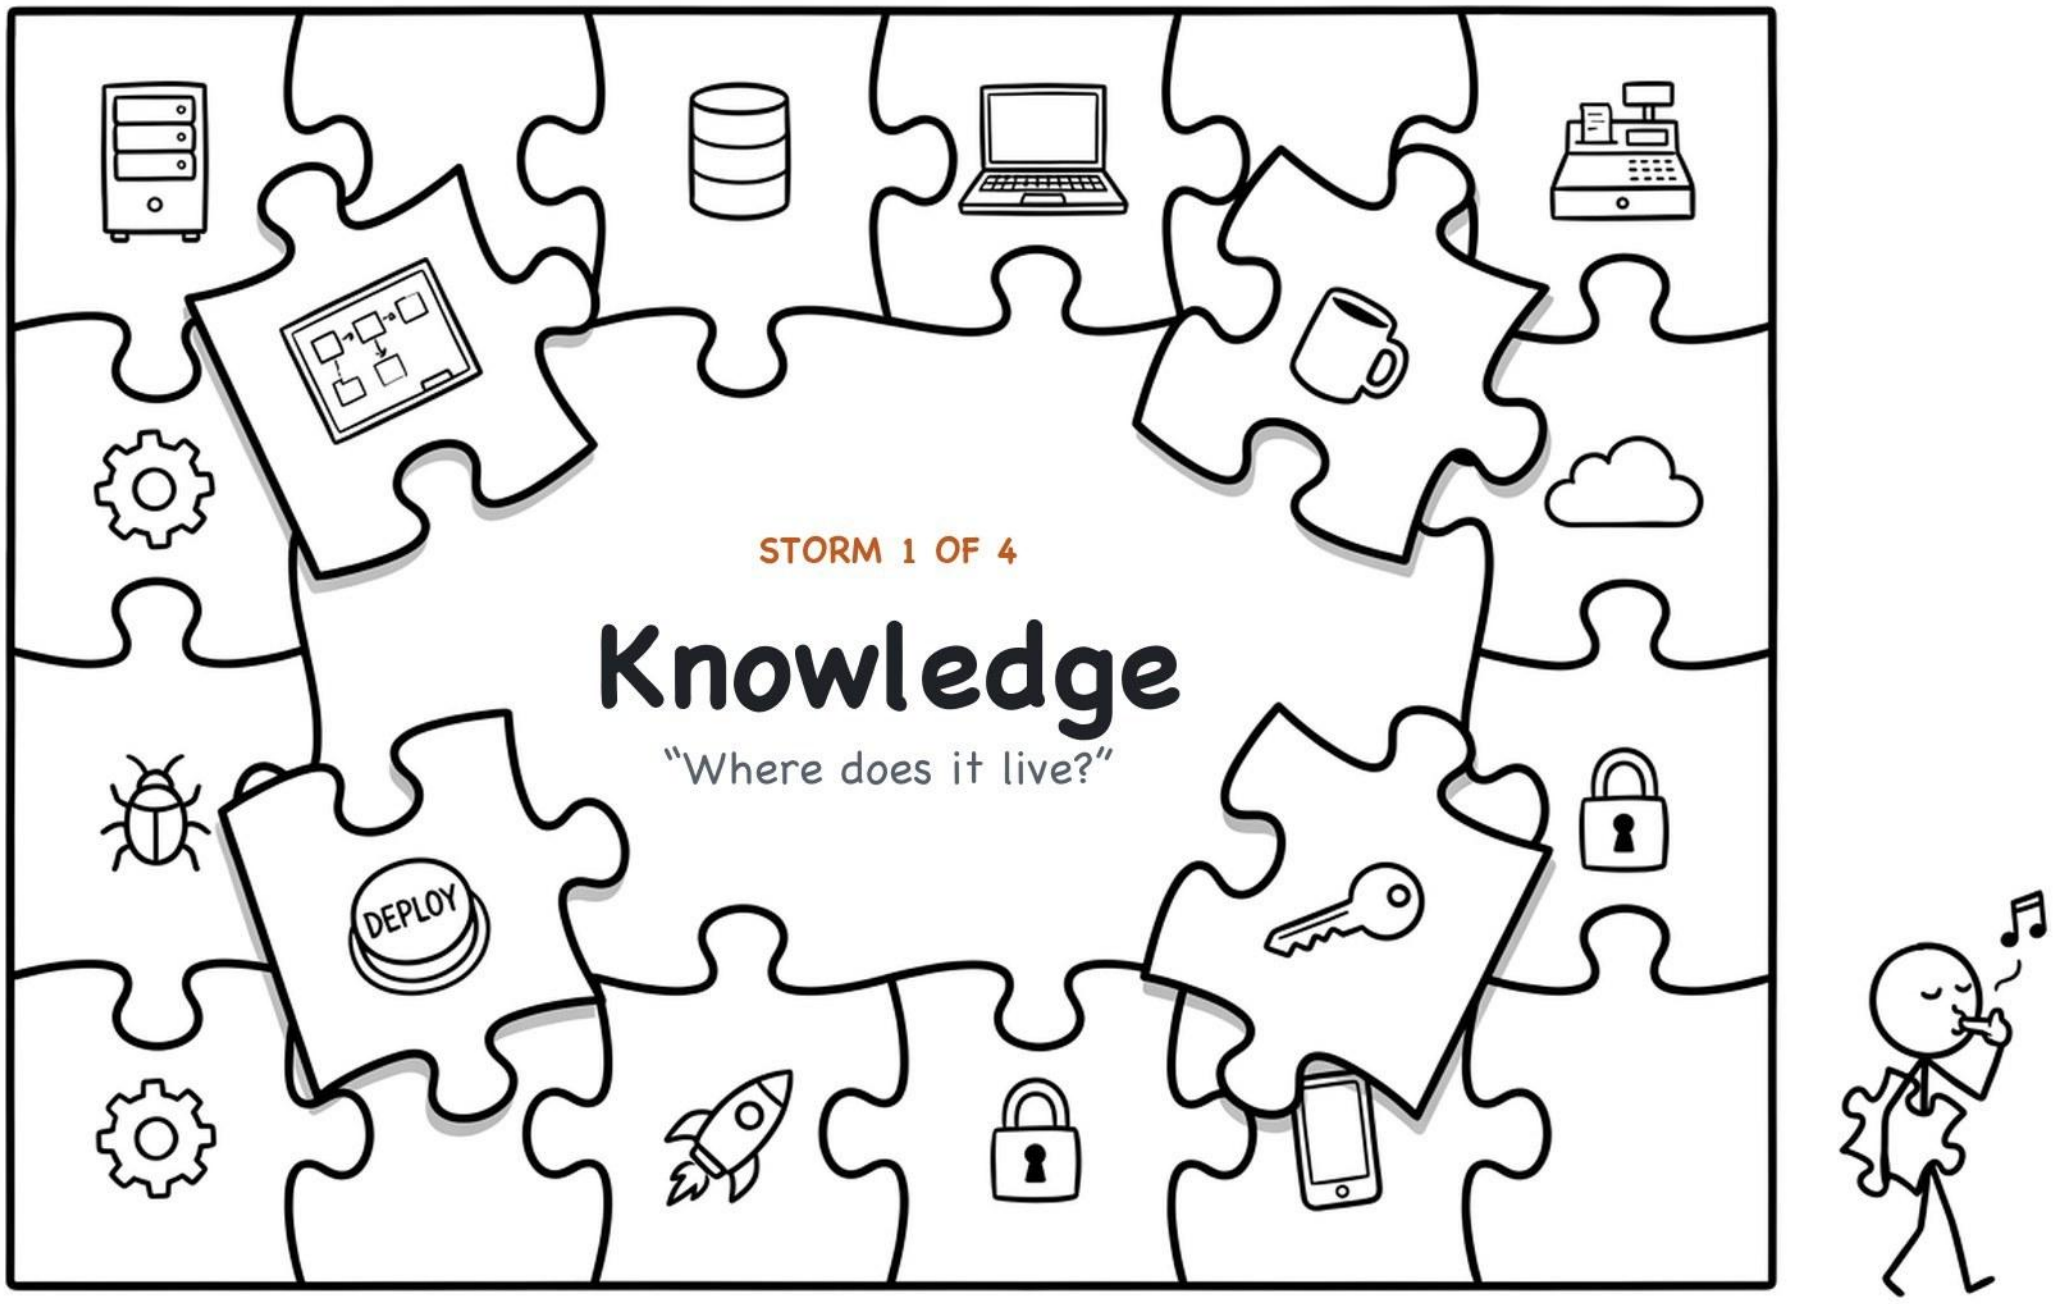

PART 3

Avoiding Complete Chaos

Every hurricane starts as a little storm

Part 3: Avoiding Complete Chaos. We can't get rid of the trade-off, but we can manage it. Every hurricane starts as a little storm: a small, sensible-looking step that nobody breaks up, until it organizes into chaos. Here are the little storms to watch for.

Storm 1 of 4: Knowledge. The first little storm: where knowledge lives. When it lives in one head, every vacation is a partition.

Merge Conflicts in Our Heads

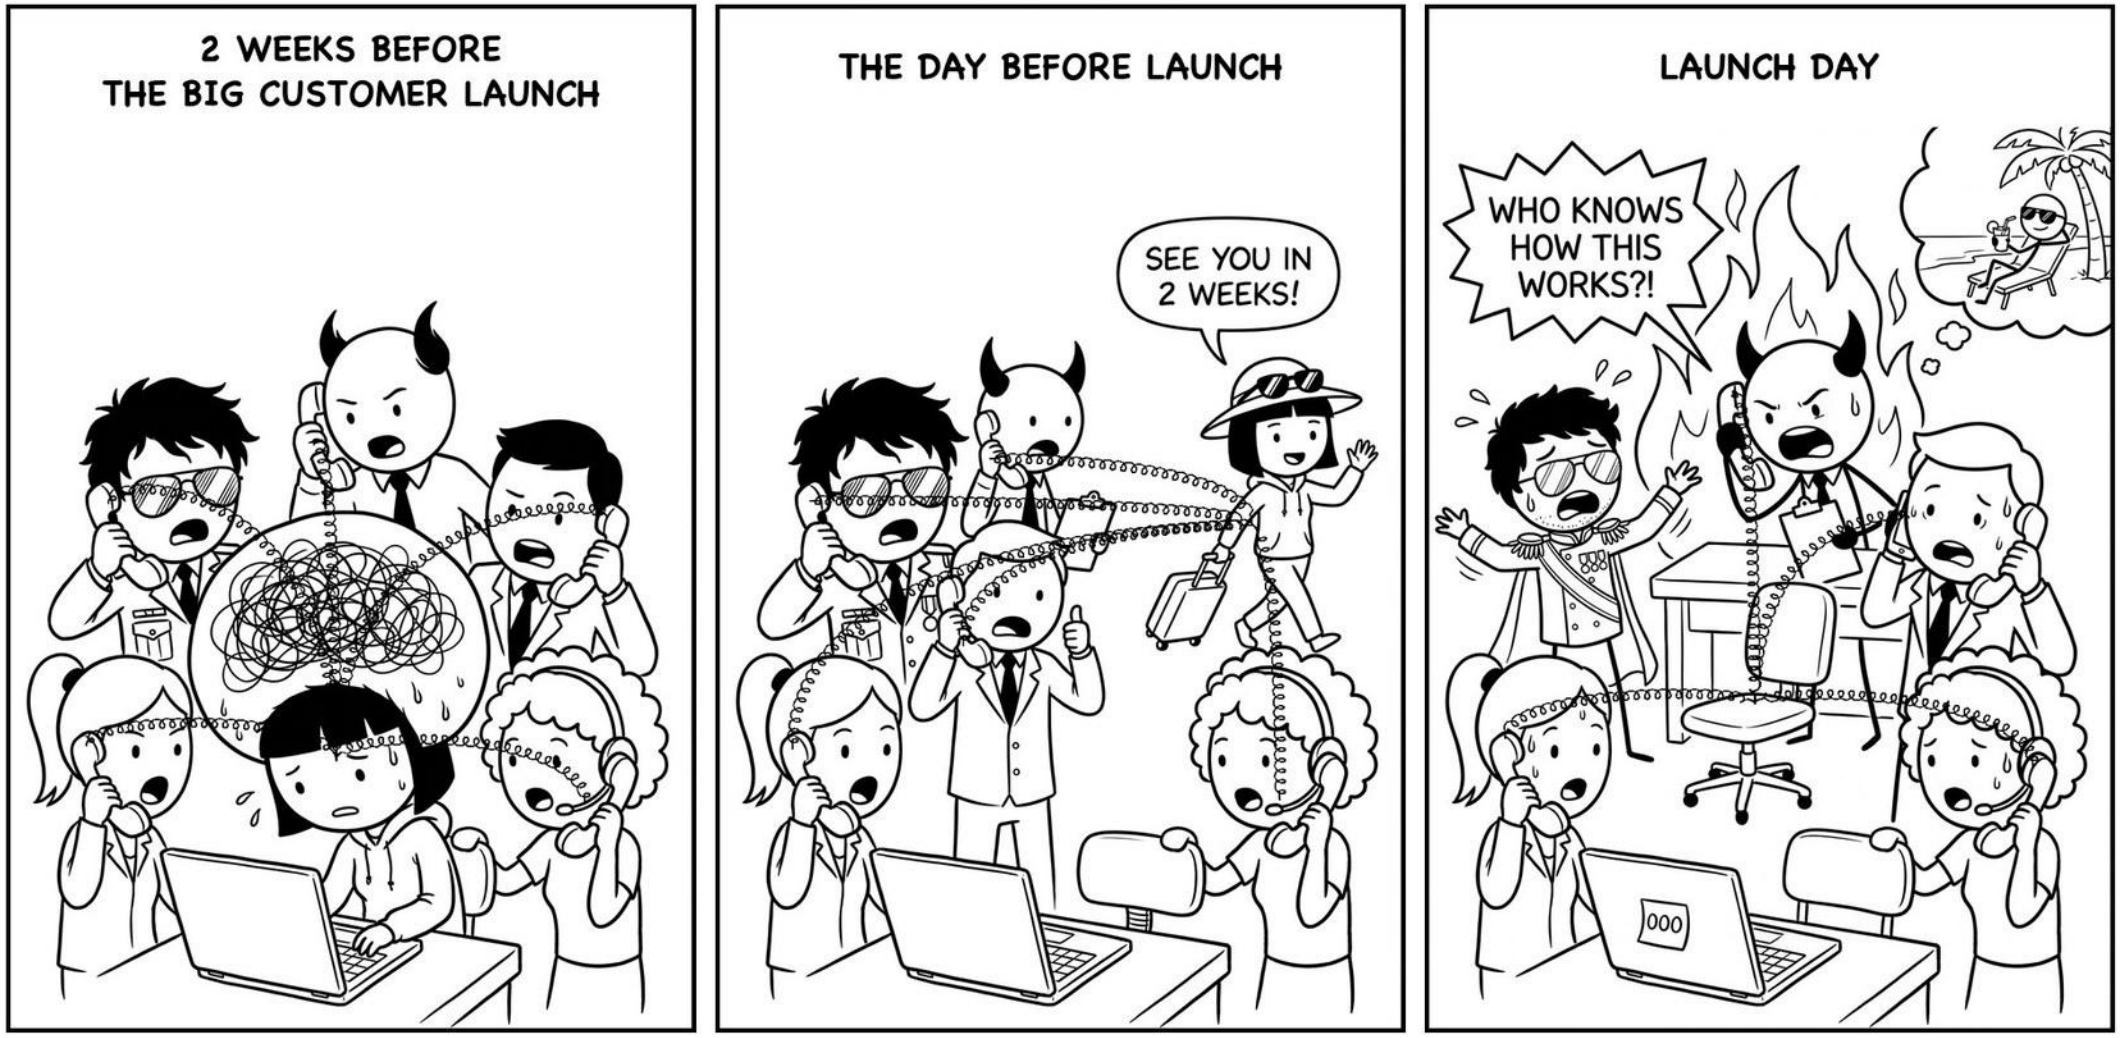

Merge conflicts in our heads. Two smart people, both talking to customers, both sure they know what the next feature is. One has heard "we lose hours counting cash"; the other has heard "we can't trust the loss numbers." Neither is wrong. But each has been building on their own version for weeks, and by the time it surfaces in a planning meeting it isn't a question anymore, it's a fight about who's right.

Continuous Conflict Resolution

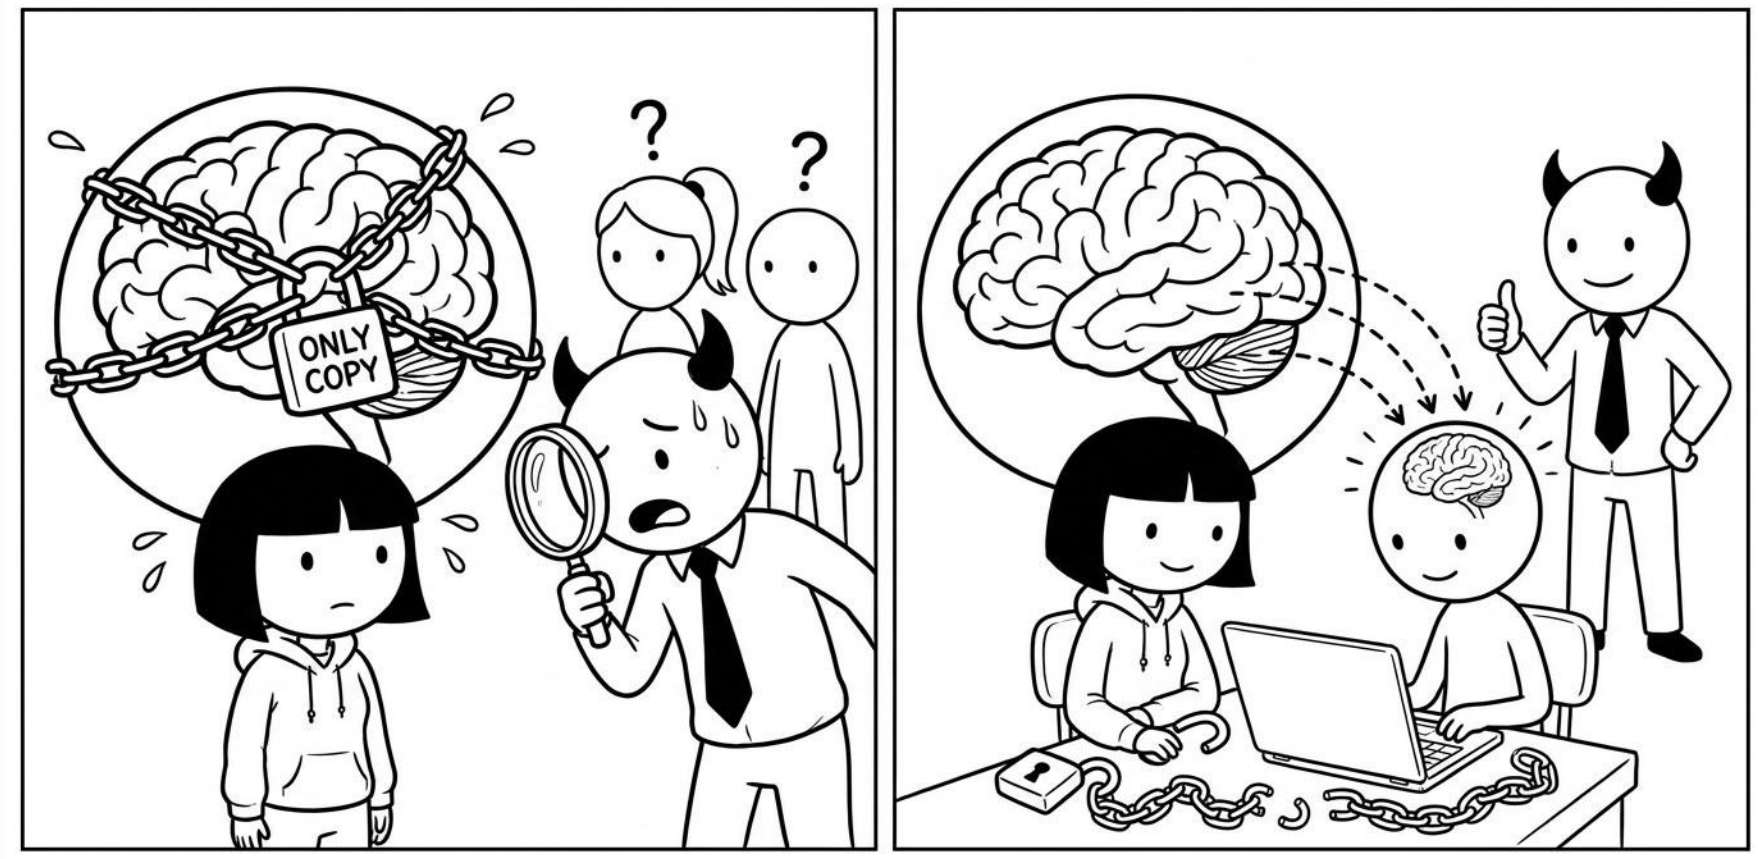

Continuous conflict resolution. Go looking for disagreements early, while they're still small. When two people describe the same feature differently in a one-on-one, that's the moment: put them in a room the same week, and start with the facts, not the solution. What did the customer actually say? What does the data show? Once they see the same reality, the answer is usually obvious, and often it's both. A disagreement found in week one is a coffee; found in month three, it's a reorg.

The Hero Dependency

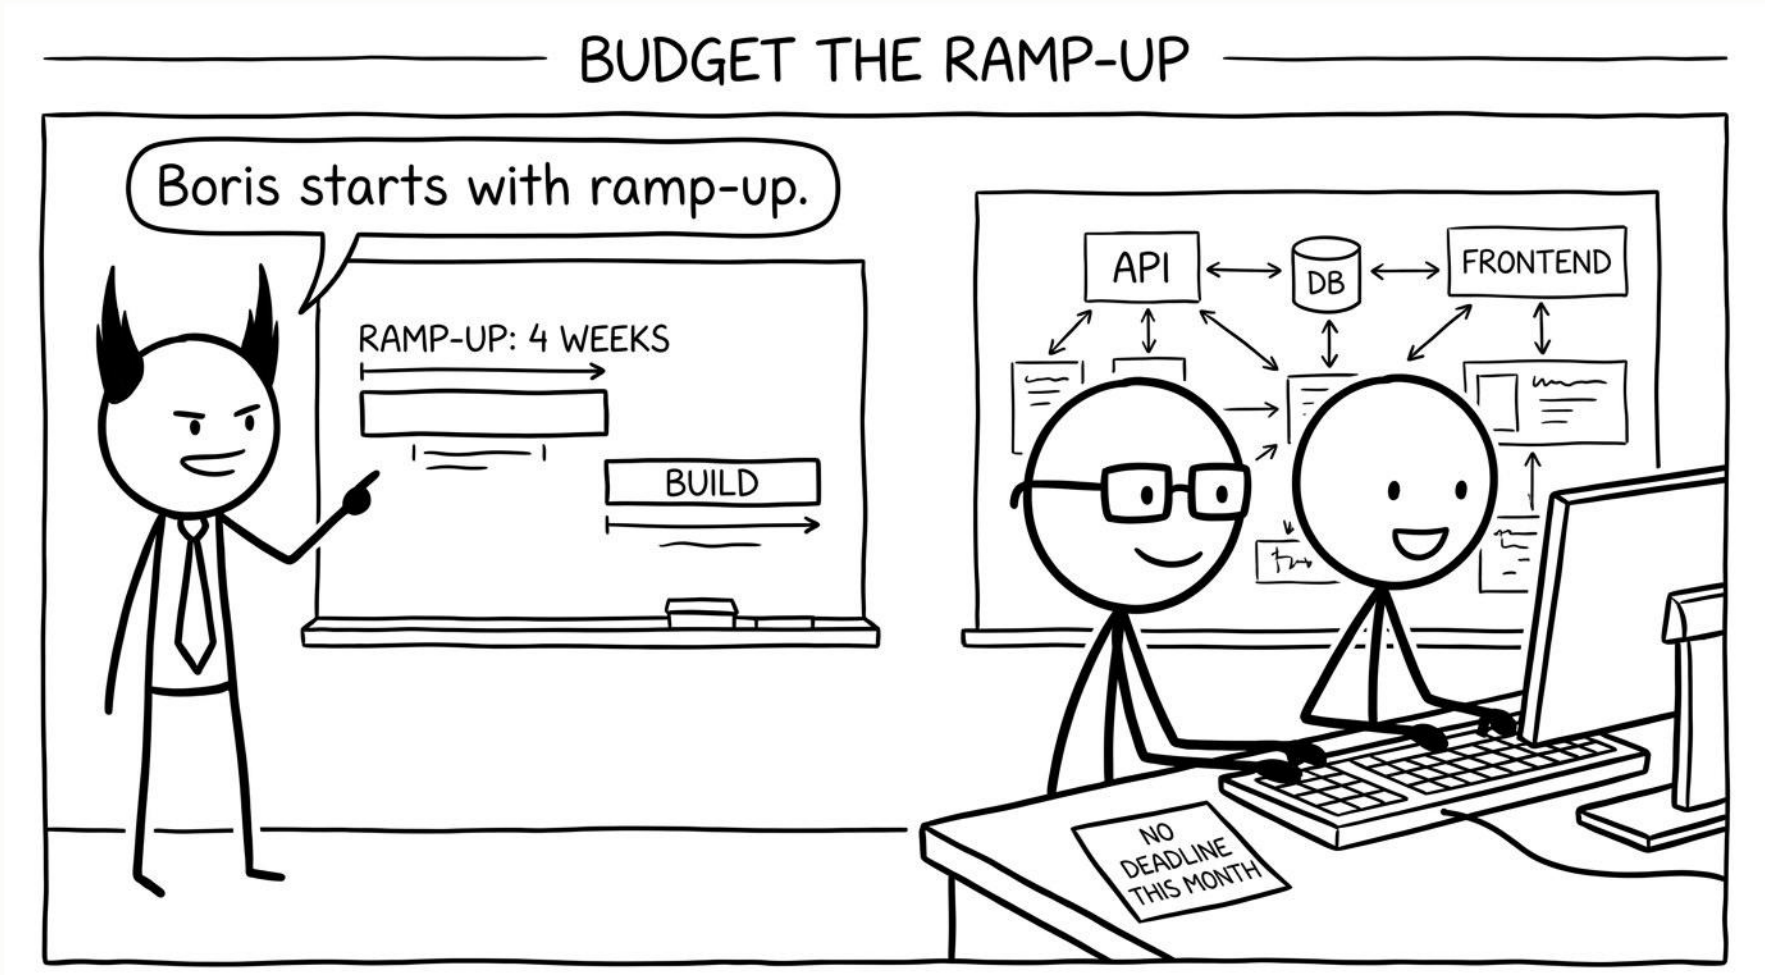

The hero dependency. One engineer built the whole integration for our biggest new customer, so every question, from the CEO to Support, goes to their head. Then they go on PTO exactly as we launch. Nobody else knows how it works, and the launch catches fire. When knowledge lives in one head, that person is a single point of failure.

Cross-training to Remove Siloes

Cross-training to remove siloes. Know where knowledge is stuck: the one person who understands billing, the deploy script only one person can run. A bus factor of one is a bug. Fix it on purpose: pairing, rotation, writing it down, before that person goes on PTO.

Budget the ramp-up. Moving an engineer isn't free. Put the ramp-up on the plan: a few weeks pairing with someone who knows the system, with no deadline attached. It's slower at first, and much faster than pretending.

STORM 2 OF 4

Direction

"What matters?"

Storm 2 of 4: Direction. The second: nobody agrees on what matters. Without a shared answer, every request looks equally important, and the engineers end up refereeing.

Strategy Nobody Understands

Strategy nobody understands. The strategy gets presented in the boardroom as a list of buzzwords. Every engineer walks away with a different guess about what it means, so they all build something different, and the customers walk out to the competition.

Strategy is a filter. Without a strategy, all opinions could be valid, and the engineer has to referee. With a strategy, like "Full POS for C-stores", individuals can filter out the requests that don't match the overall goals. An AWS outage always gets through. Cash refunds are core POS, so they're in. A self-order tablet or a Square integration might be good ideas, but they're not this strategy: not yet. No meeting, no escalation.

Everything Is Top Priority

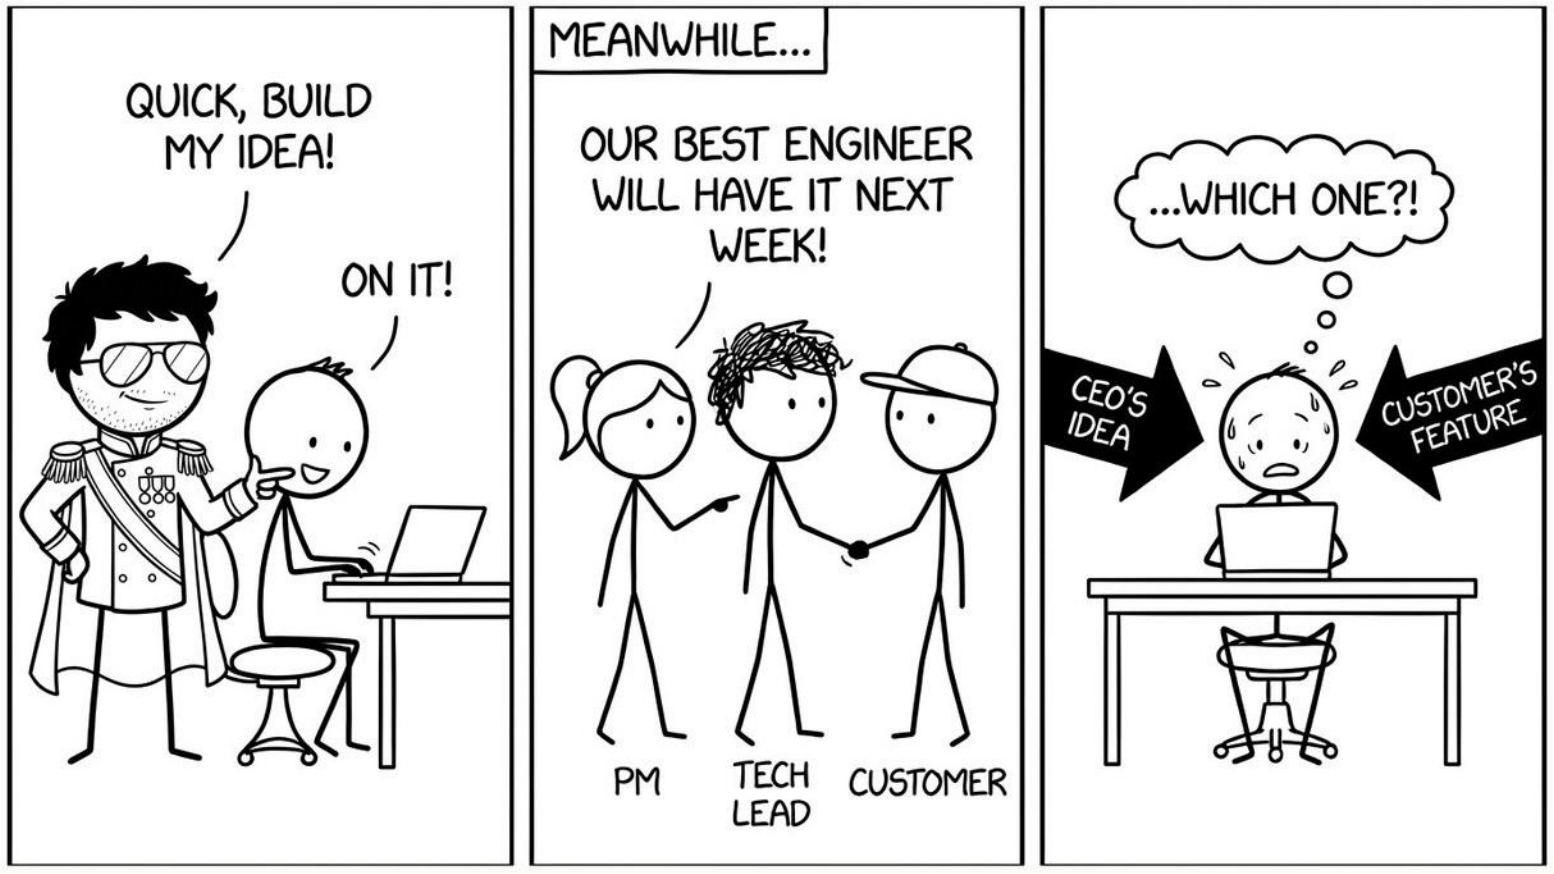

What's the top priority? The Architect, PM, Support and Sales each have a different "top priority", and they fight it out. Until they agree, the engineer has nothing to do but watch.

One prioritized list, out in the open. One prioritized list, communicated publicly. Everyone can still argue for their item, once, in the room, and then the order is the order. It's posted where everyone can see it and updated on a schedule, so nobody has to ask the engineers what they're working on, and the engineers don't have to referee.

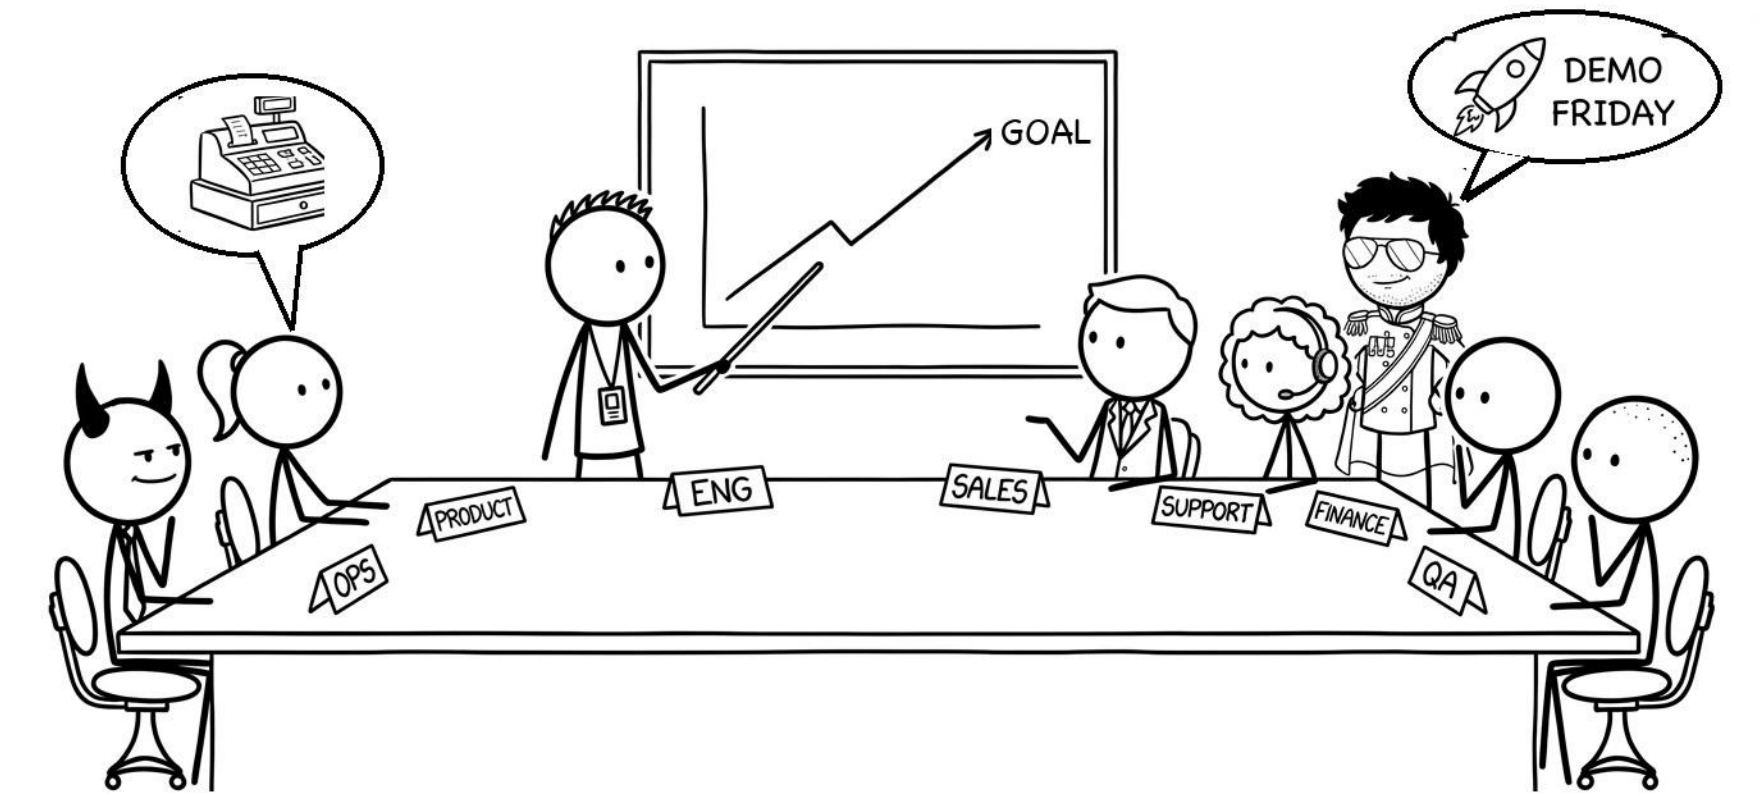

The CEO Side Door

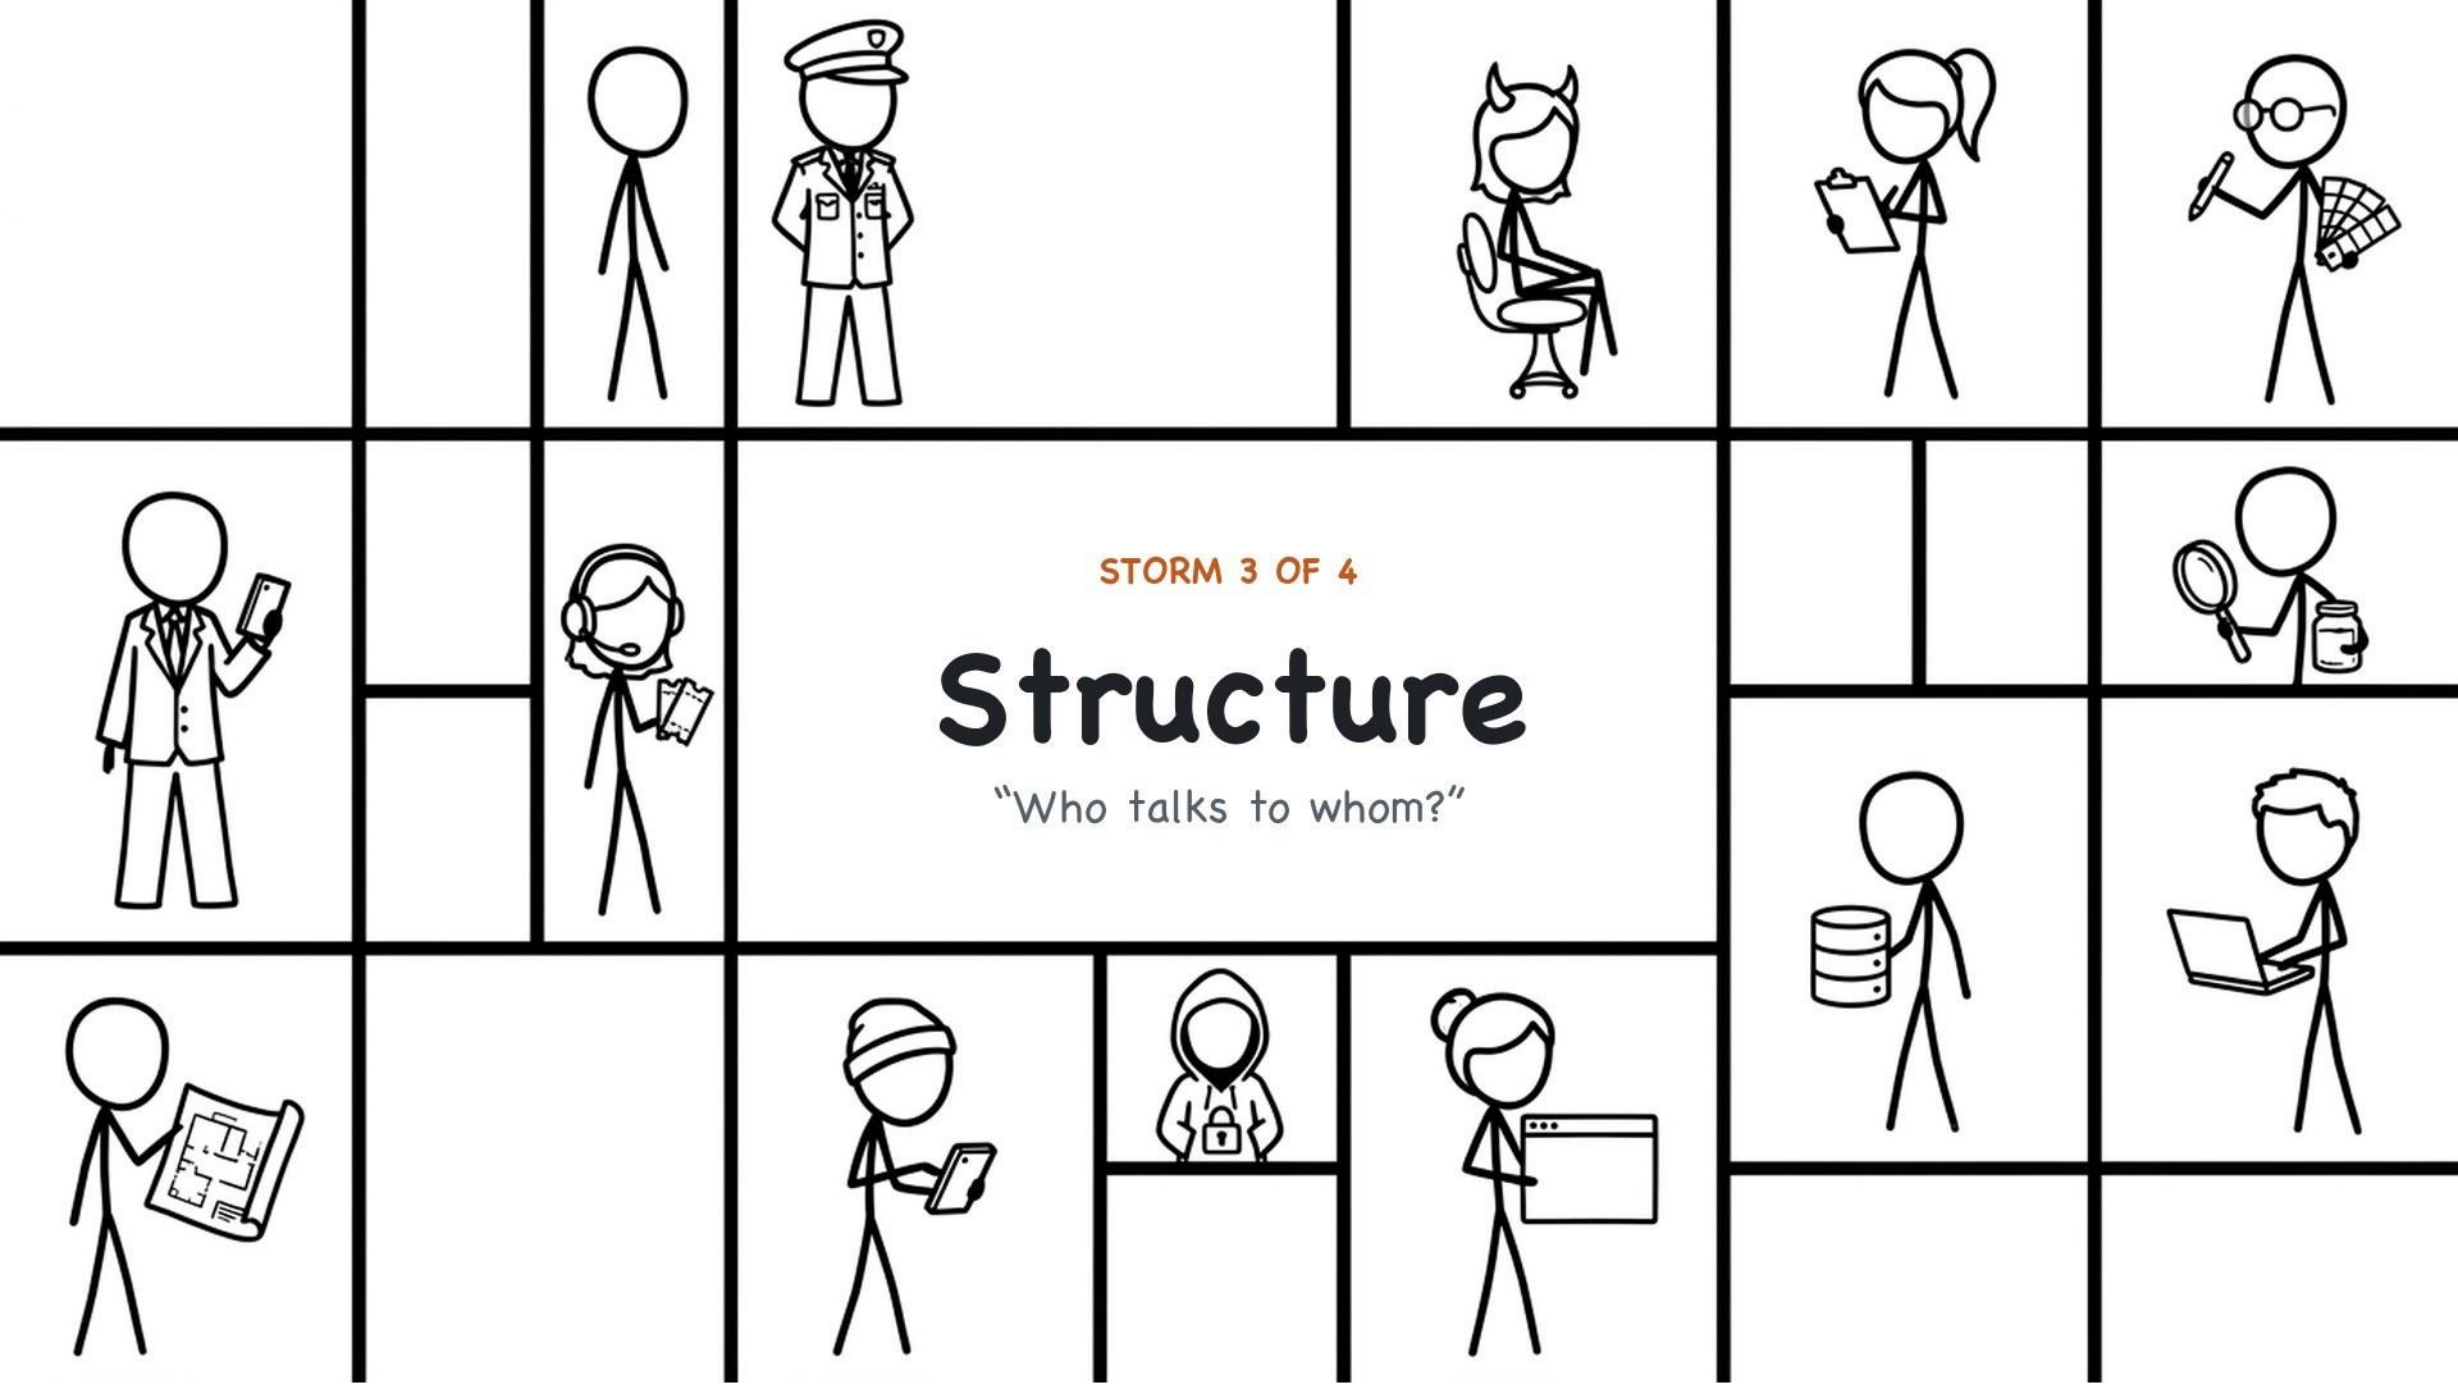

The CEO side door. The CEO grabs one engineer directly, and the engineer happily starts. Meanwhile, the PM and tech lead promise a customer a feature from the very same engineer. Nobody knows about the other promise until the engineer is stuck between them.

CUSTOMER WEEKLY · STORE HEALTH

Everyone who can affect a major goal. Weekly. No excuses for the BUSINESS not to be aligned.

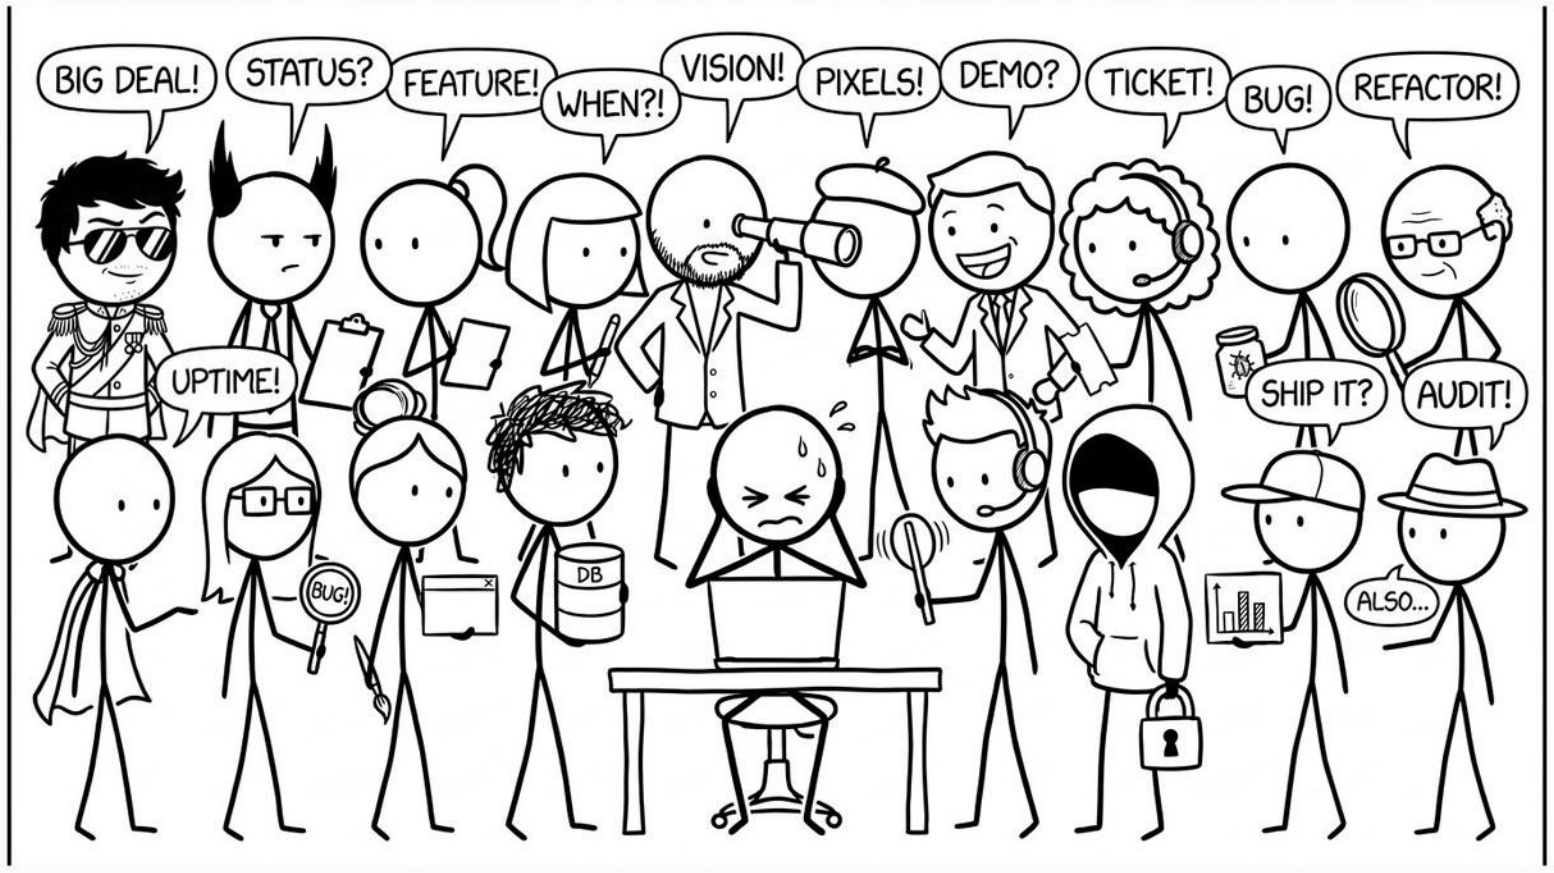

Cross-functional goal meetings. Weekly or bi-weekly, with everyone in the company who can affect a major goal: Customer Weekly, Store Health, and so on. No excuses for the business not to be aligned.

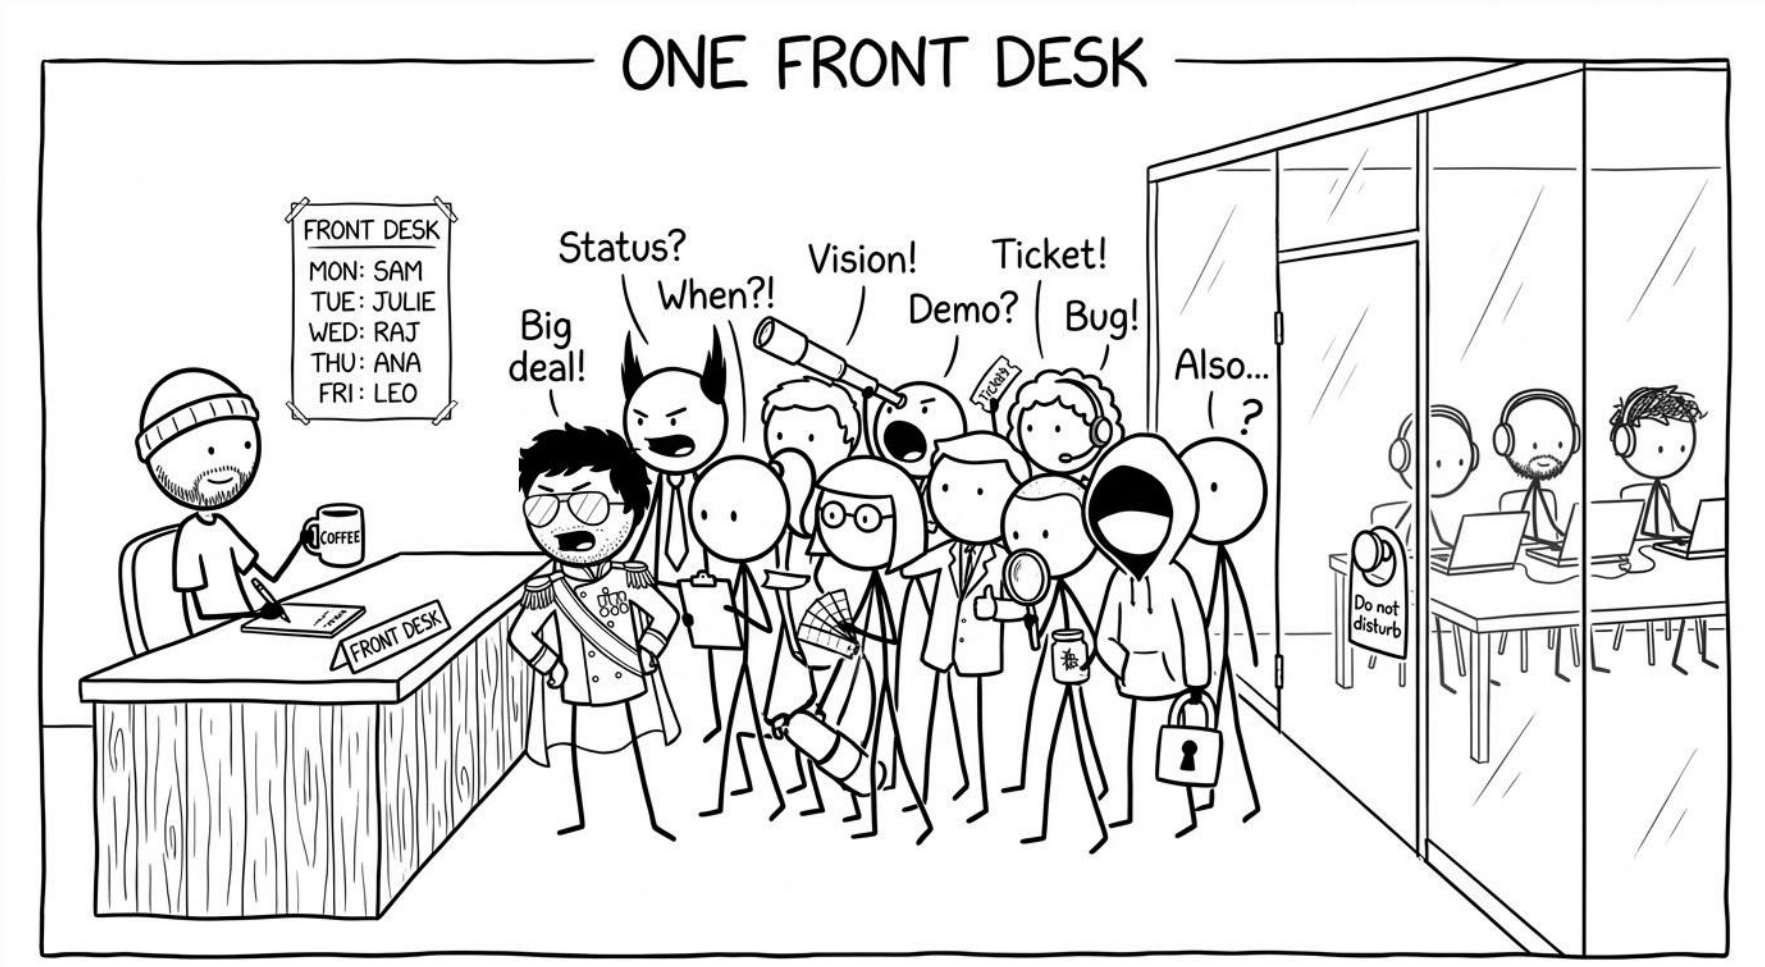

Storm 3 of 4: Structure. The third: the wiring. Who talks to whom, how many lines run through each person, and who owns what.

Everyone Piles Onto One Engineer

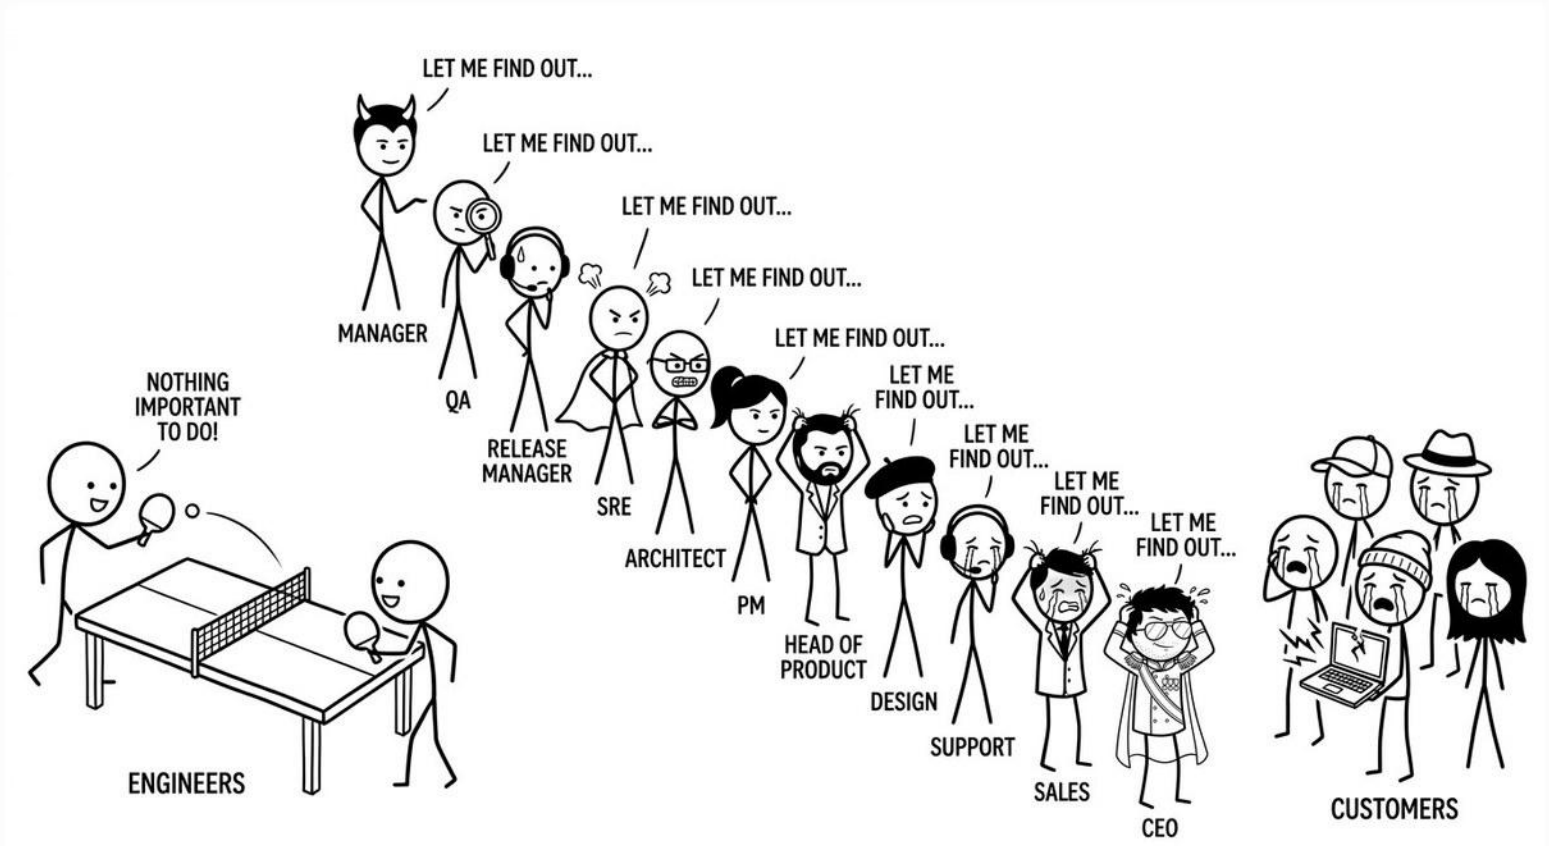

Everyone wants something. Without the structure, every role goes straight to the engineer, and they all want something different, right now. The engineer has no idea what to do first.

One front desk. Give the crowd one front door. Each day one engineer takes the front desk: every question, every ticket, every "quick thing" goes to them. They answer what they can, put the rest on the list, and everyone else gets to stay heads-down. It rotates, so nobody is stuck at the desk forever, and everybody learns the whole system.

Too Many Layers

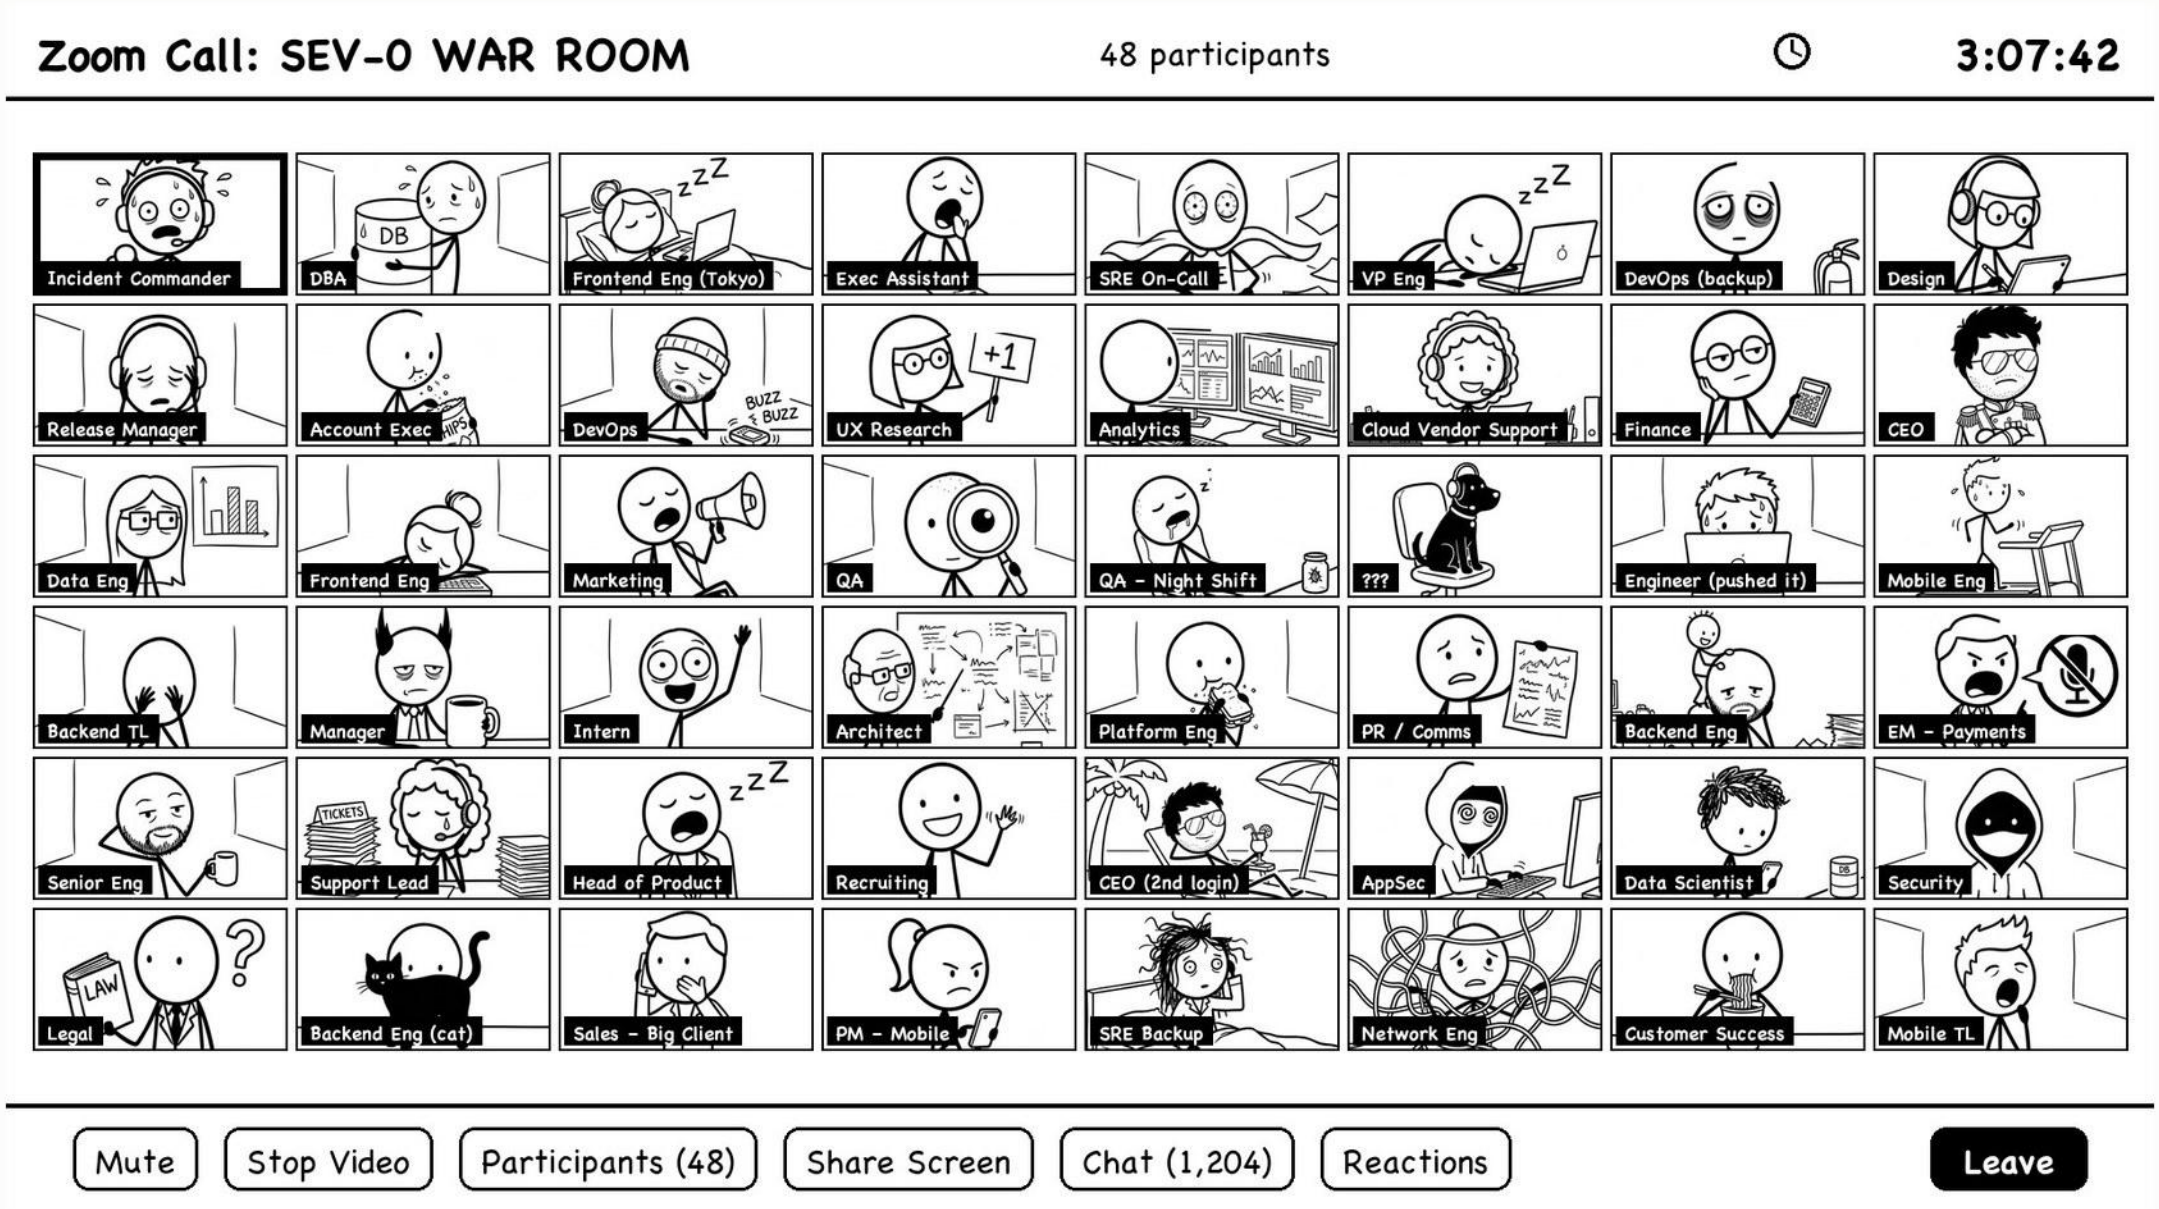

Let me find out... The opposite failure. So many layers sit between the engineers and the customers that nothing gets through: every layer says "let me find out...", frustration builds the closer you get to the customer, and the engineers think there's nothing important to do.

SOMETIMES, SHORTCUT THROUGH THE STRUCTURE

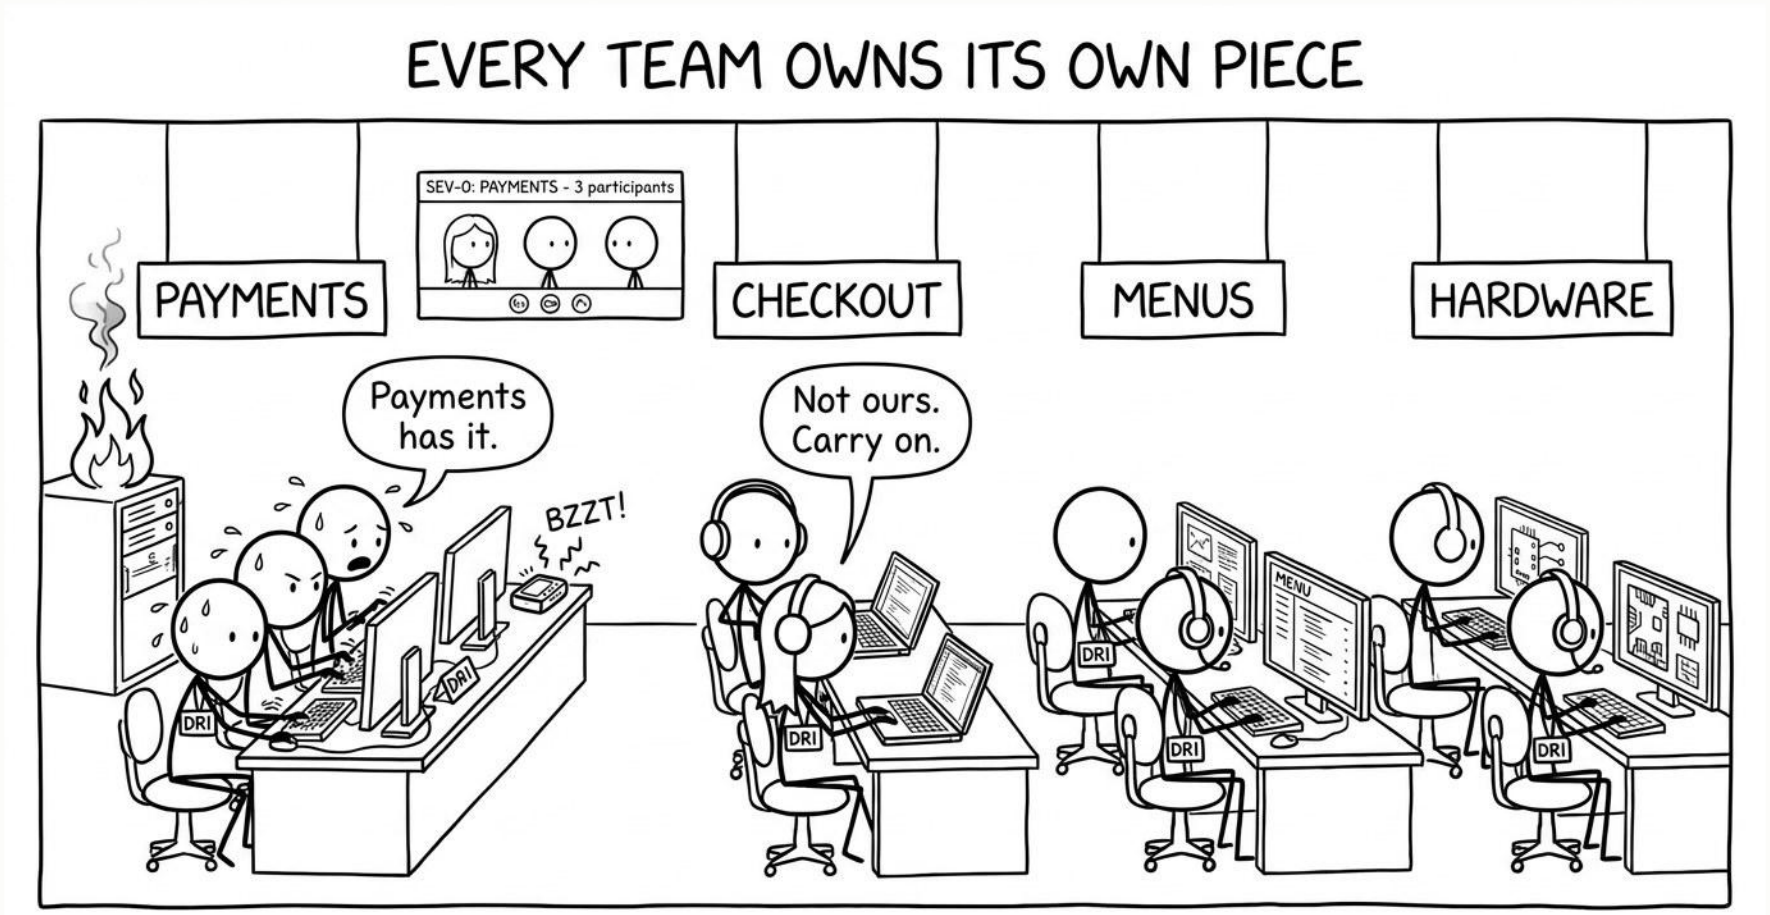

Sometimes, shortcut through the structure. We shipped engineers to a big customer's kitchens to discover the problems directly. No layers, no summaries, no "let me find out": just the people who build it, standing next to the people who use it. You don't do this every day, but when the signal keeps getting lost on the way, sometimes the fastest path is straight through the structure.

Everyone Is Responsible for Everything

If the system gets too complicated, it becomes very hard to figure WHAT and WHO is responsible for fixing it. Nobody understand the whole system anymore. A common clue that this is a problem are huge war rooms where everyone gets pulled in to help, because nobody knows who actually can.

Every team owns its own piece. The fix is ownership. Split the system into pieces, give every piece a team and every team a DRI. When something breaks, it's obvious whose it is: one team gets paged, three people join the call, and everyone else keeps working.

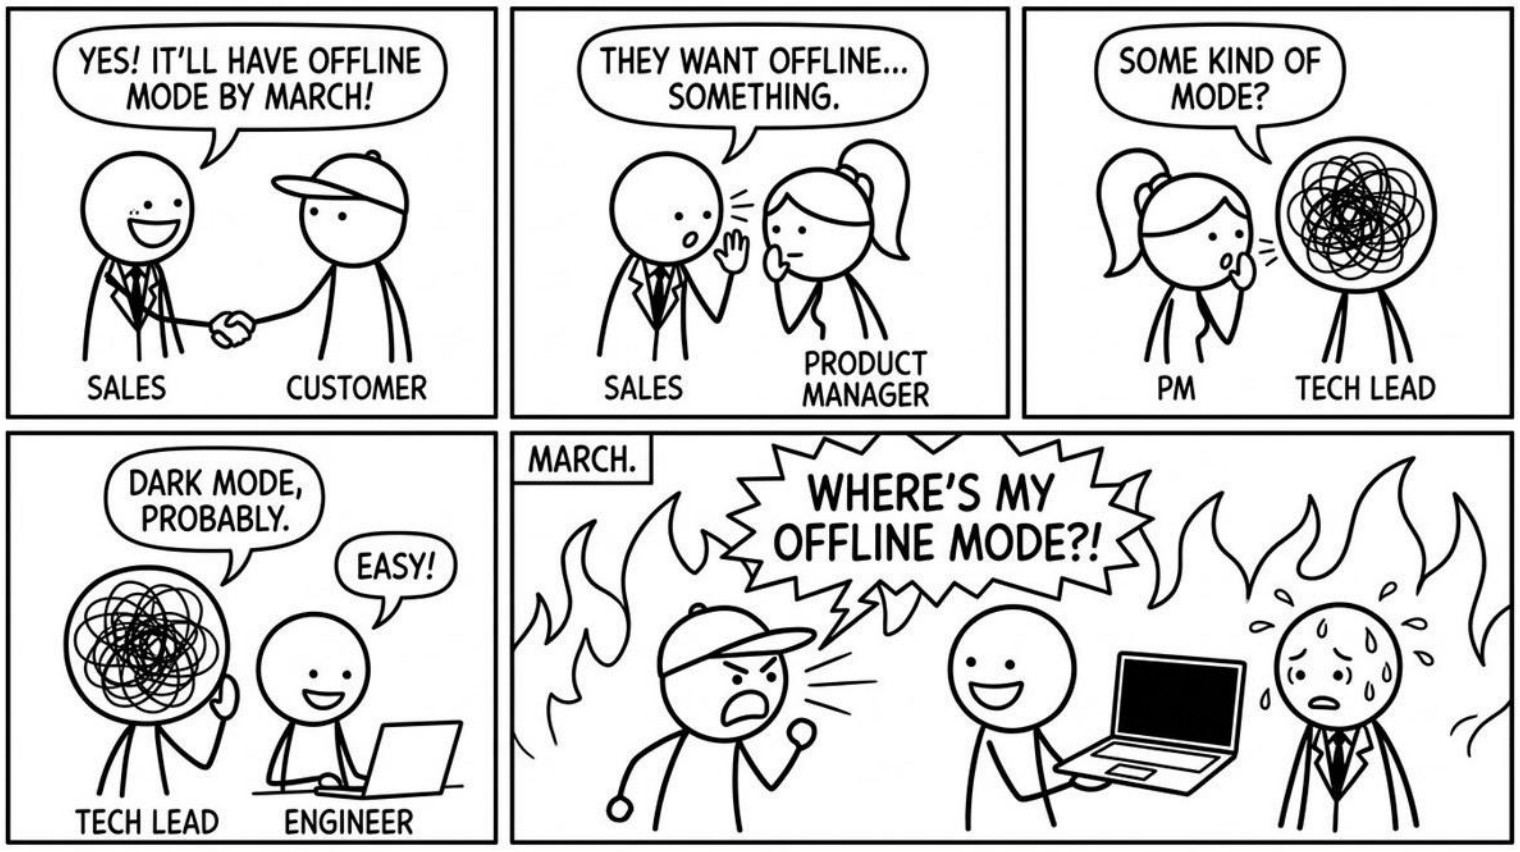

STORM 4 OF 4

Communication

"How does it travel?"

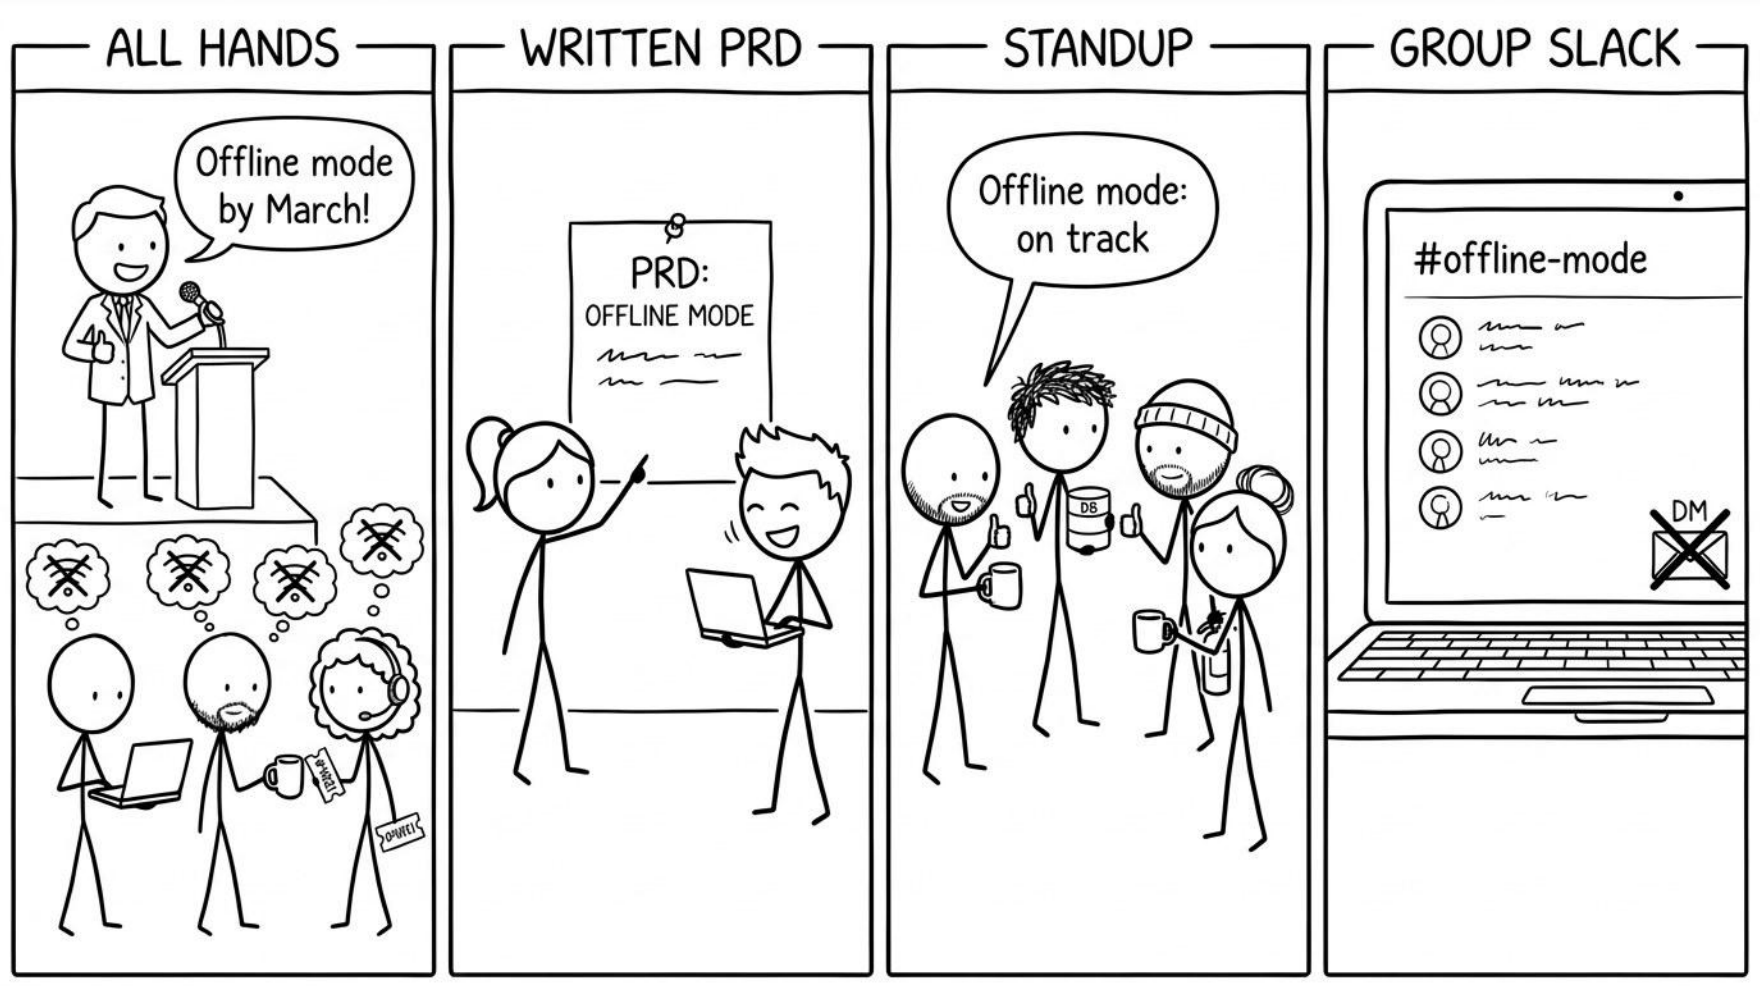

Storm 4 of 4: Communication. The fourth: how information travels. Even with the right wiring, a lossy or expensive way of talking eats the team's time.

The Telephone Game

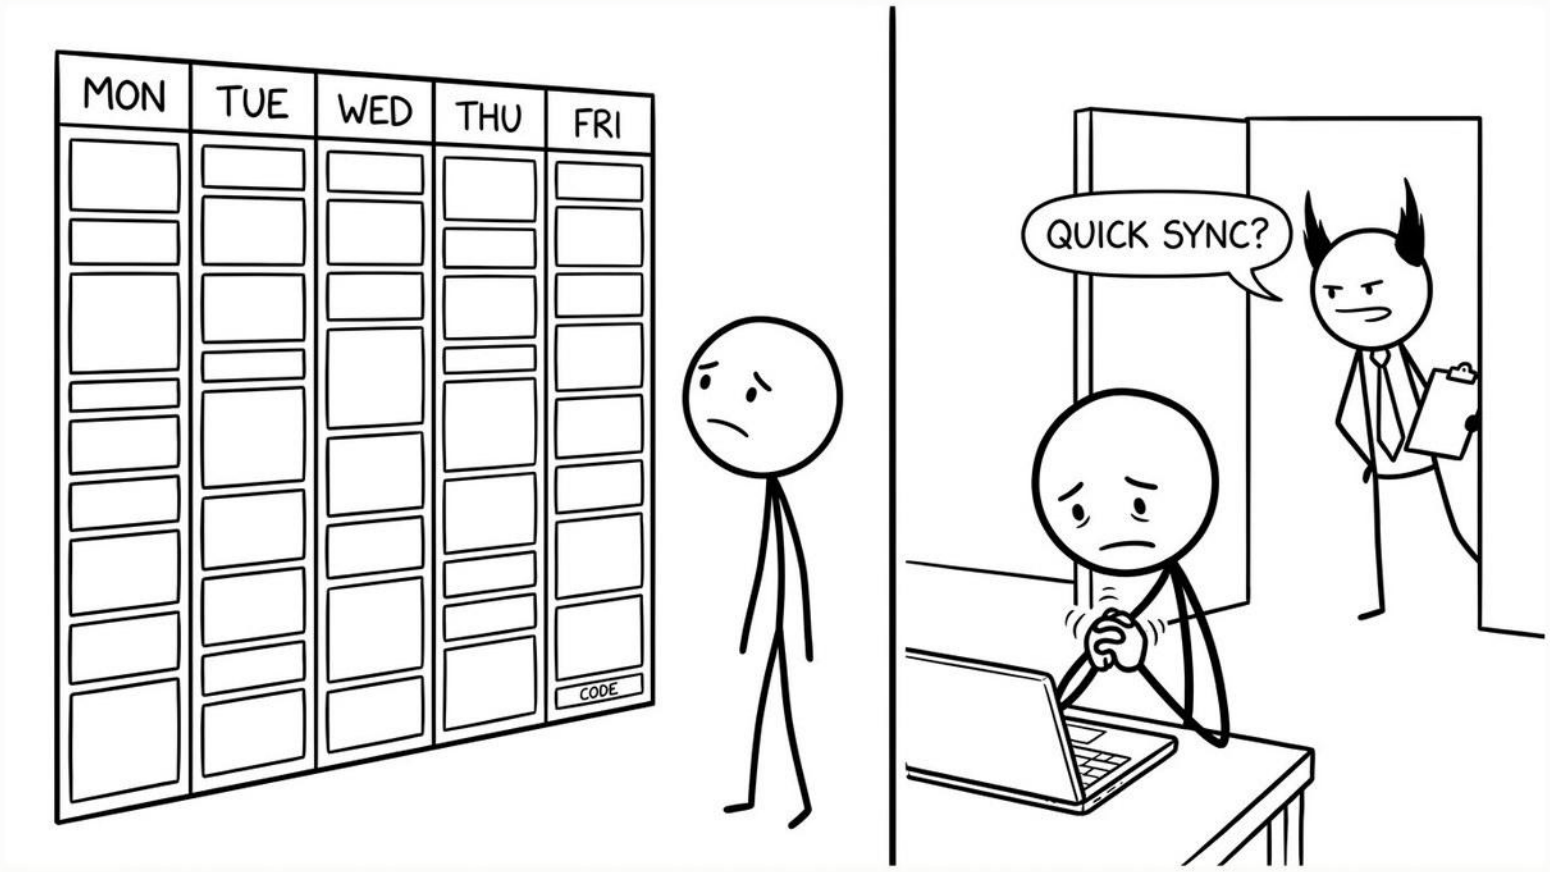

The promise that got lost. Sales promises a customer something specific. By the time it's passed through PM and tech lead, the engineer hears something else entirely, and builds that. The fire comes months later, when the customer finds out.

Beating the Telephone Game

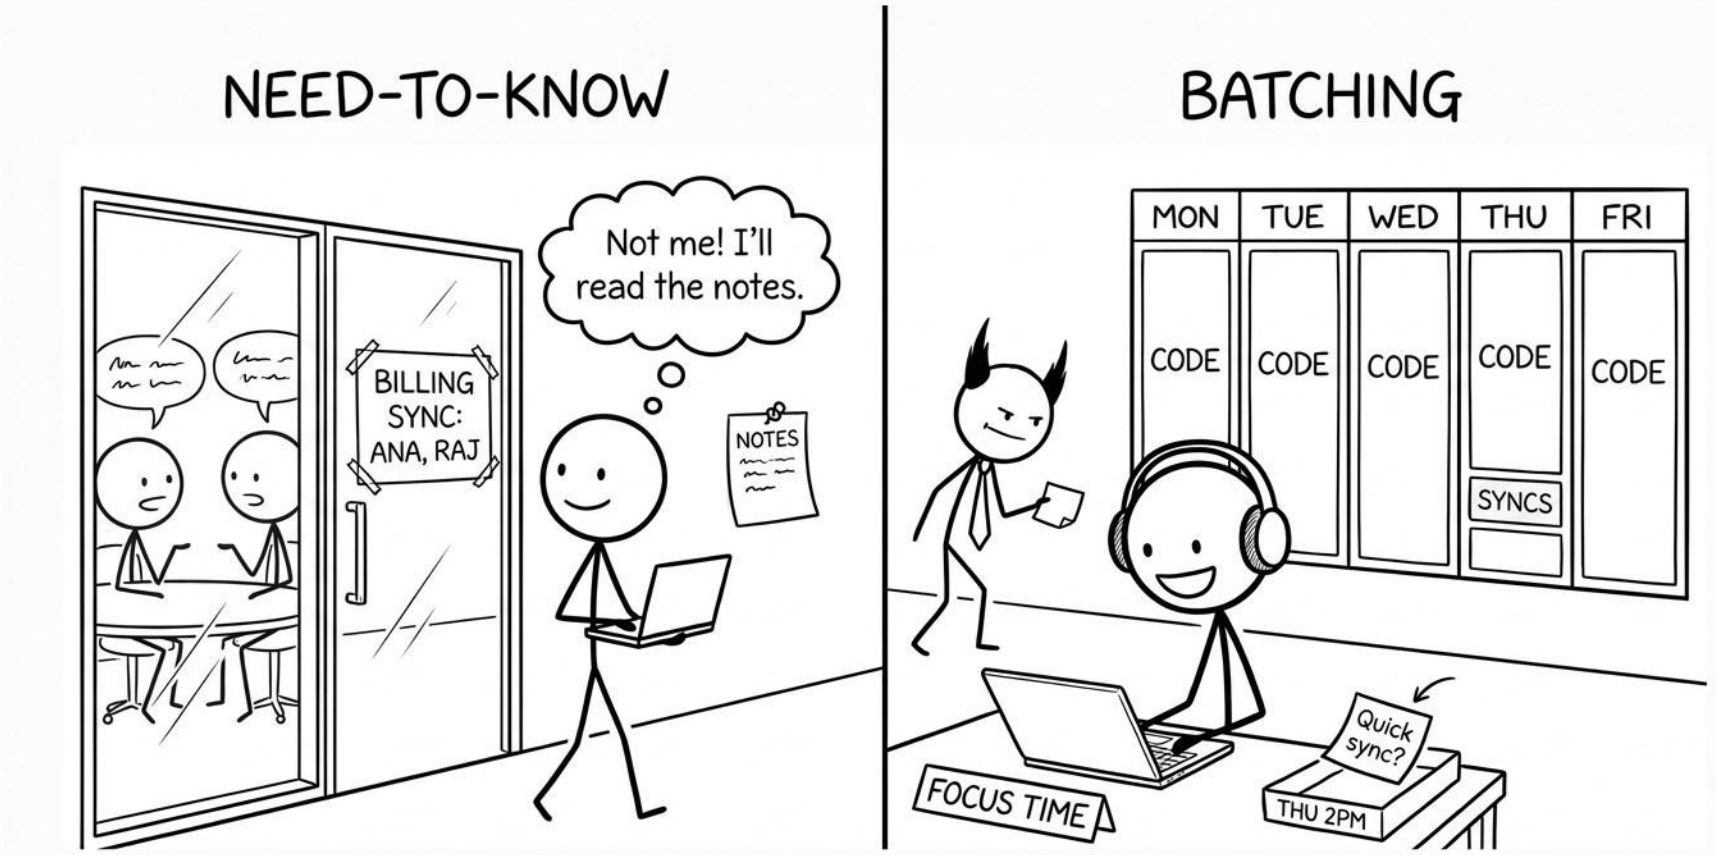

Beating the telephone game. Every hop between the customer and the engineer loses something, so cut the hops. Say the big things once, to everyone, at the all hands. Write the request down in a PRD, so the engineer reads what the customer actually asked for instead of a retelling. Use standups to catch drift early, while it's still cheap to fix. And keep the conversation in a shared channel, not DMs: a DM is a private copy of the truth that nobody else can check.

Meeting Creep

Meeting creep. Every coordination problem gets "solved" with another recurring meeting: a sync, a standup, a planning session, a retro. Each one makes sense on its own. Together they leave engineers a sliver of Friday to actually build anything, and even that gets a "quick sync".

Fixing Meeting Creep

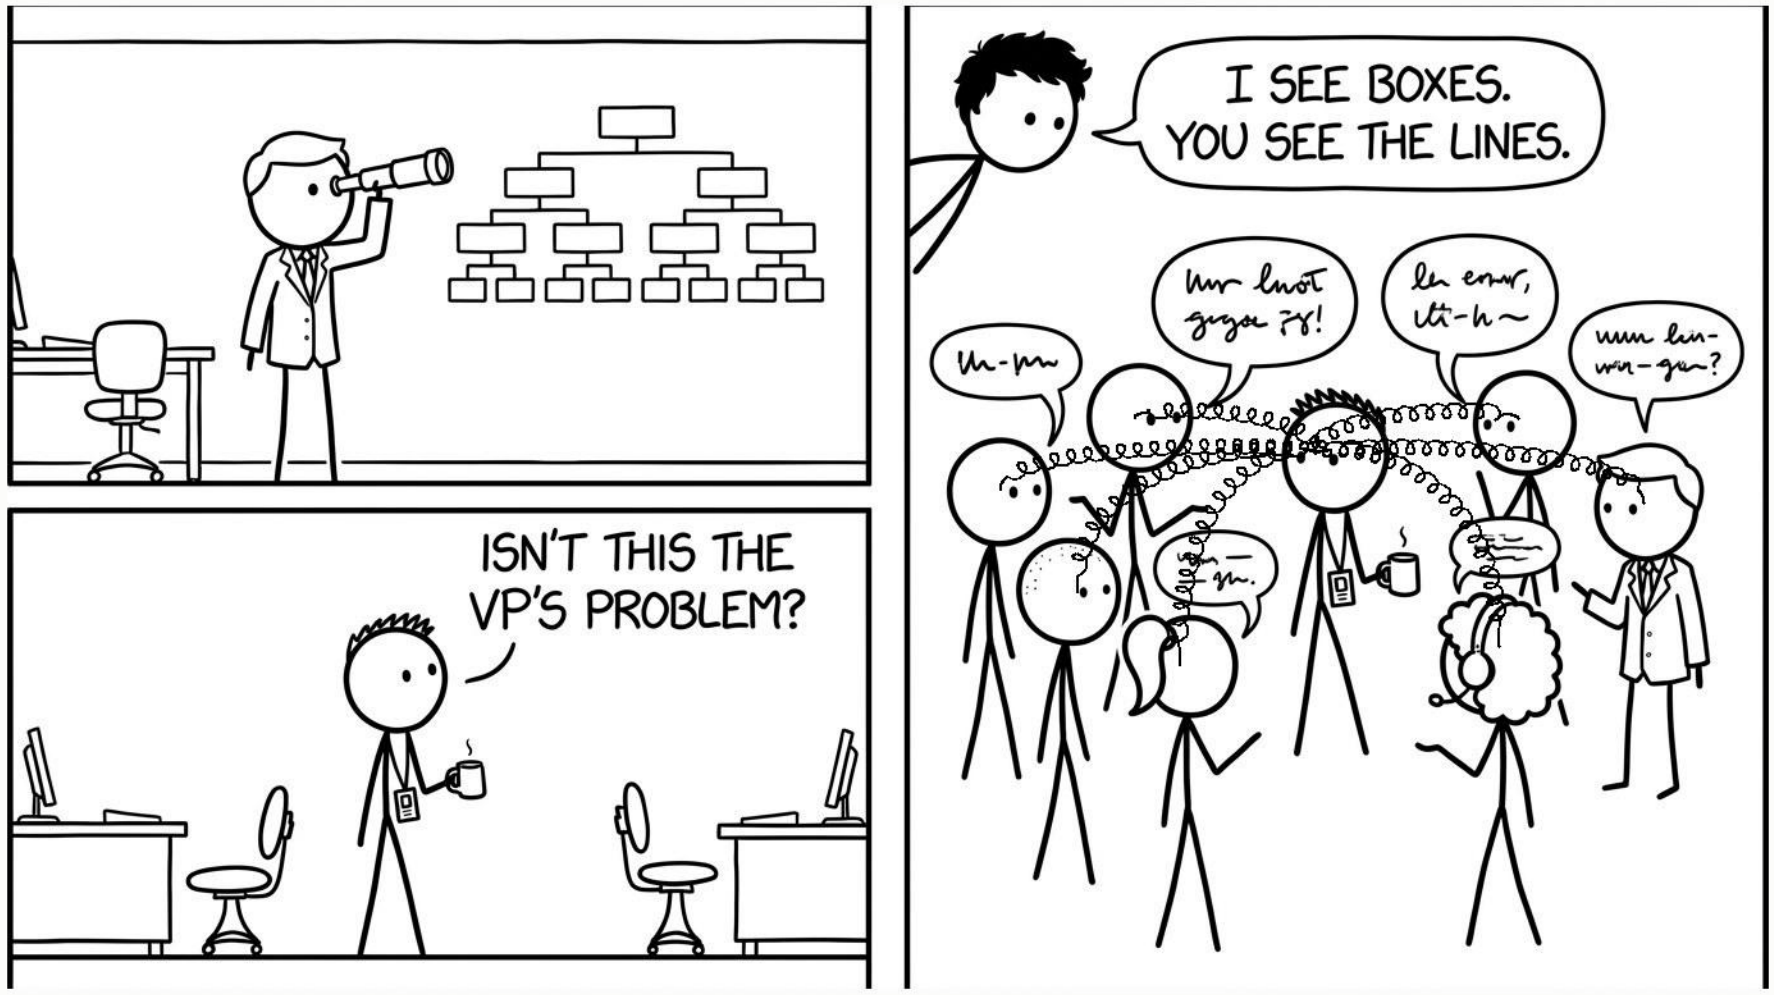

Fixing meeting creep. First, need-to-know: not everyone needs to know everything. Invite the two people who own the decision, write it down, and let everyone else read the notes when they need them. Second, batching: collect the "quick syncs" and the questions into one slot a week, and protect the rest as focus time. An interruption costs far more than the five minutes it takes; it costs the hour it took to get into the problem.

PART 4

The EM's Responsibility

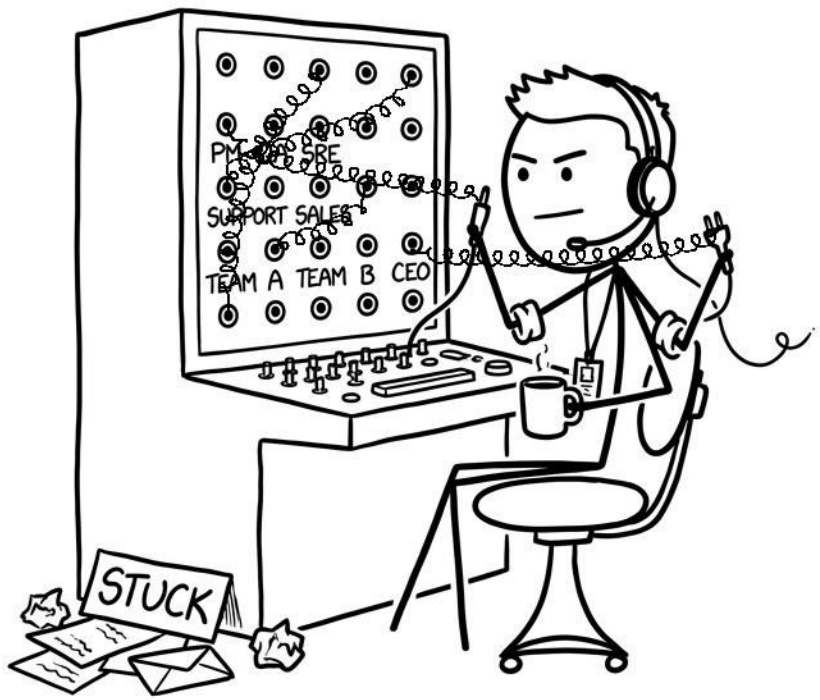

(Yes, you.)

Part 4: The EM's Responsibility. So what does this mean for you, the engineering manager?

Isn't this the VP's problem? Isn't this the VP's problem? Why do I need to think about this? Because the VP sees the org chart, the boxes. You see the lines: most of the N^2 phone lines in the org run through your team, and through you.

WHO needs to know WHAT, WHEN — and WHY?
WHERE are they going to learn it?

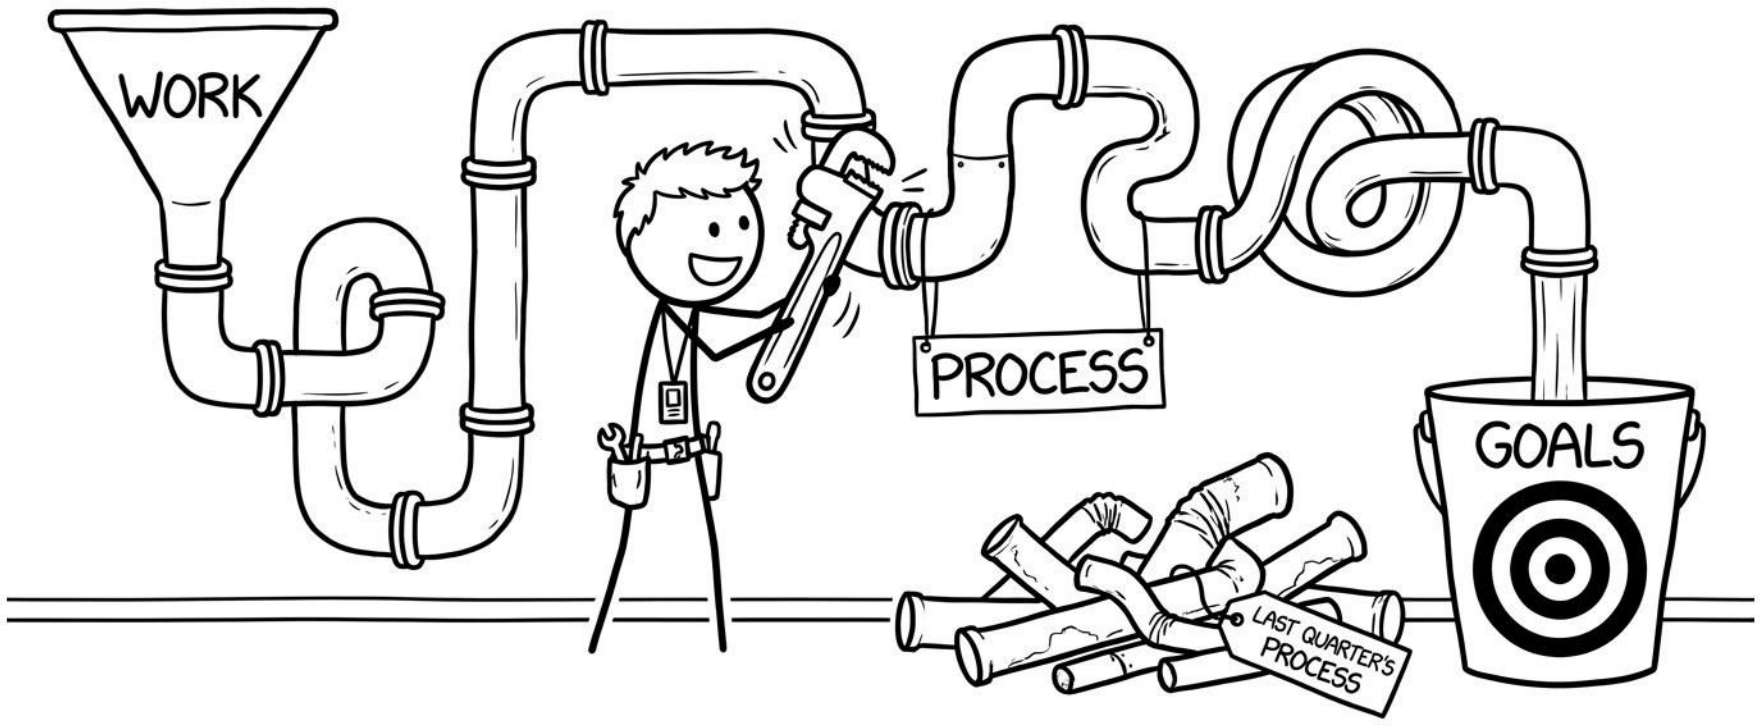

Yes, you're just
a fancy router.
(Sorry.)

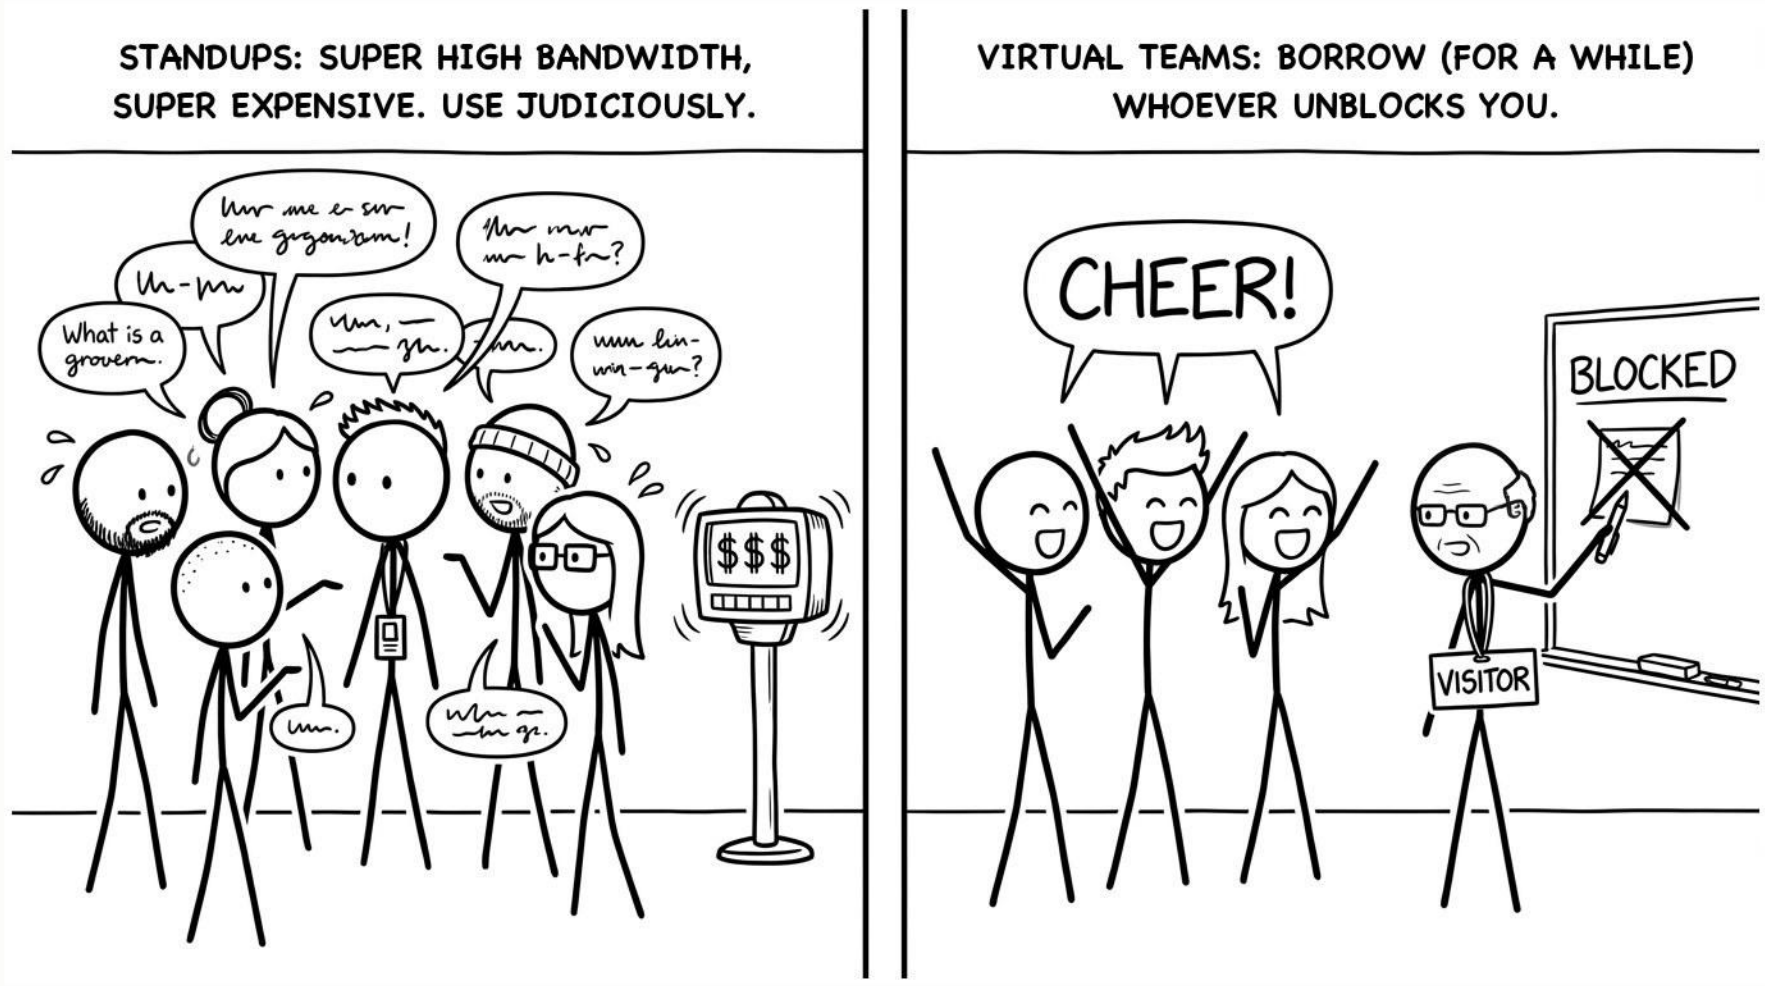

Who needs to know what, when, and why? WHO needs to know WHAT, WHEN, and WHY? WHERE are they going to learn it? If you don't have this mental model, then you can't help the system become eventually consistent, and knowledge gets stuck. Yes, you're just a fancy router. Sorry.

SHAPE PROCESS TO FIT GOALS

...and be comfortable changing it.

Shape process to fit goals. Process is plumbing: it exists to get work to the goals. When the goals change, change the process. Be comfortable throwing out last quarter's pipes.

Standups and virtual teams. Standups are expensive, synchronous events, and super high bandwidth. Use them judiciously, and get the right people in the room. Virtual teams are great: bring in, temporarily, the people who unblock you.

THE EM'S CHECKLIST

Four storms to watch for, every week.

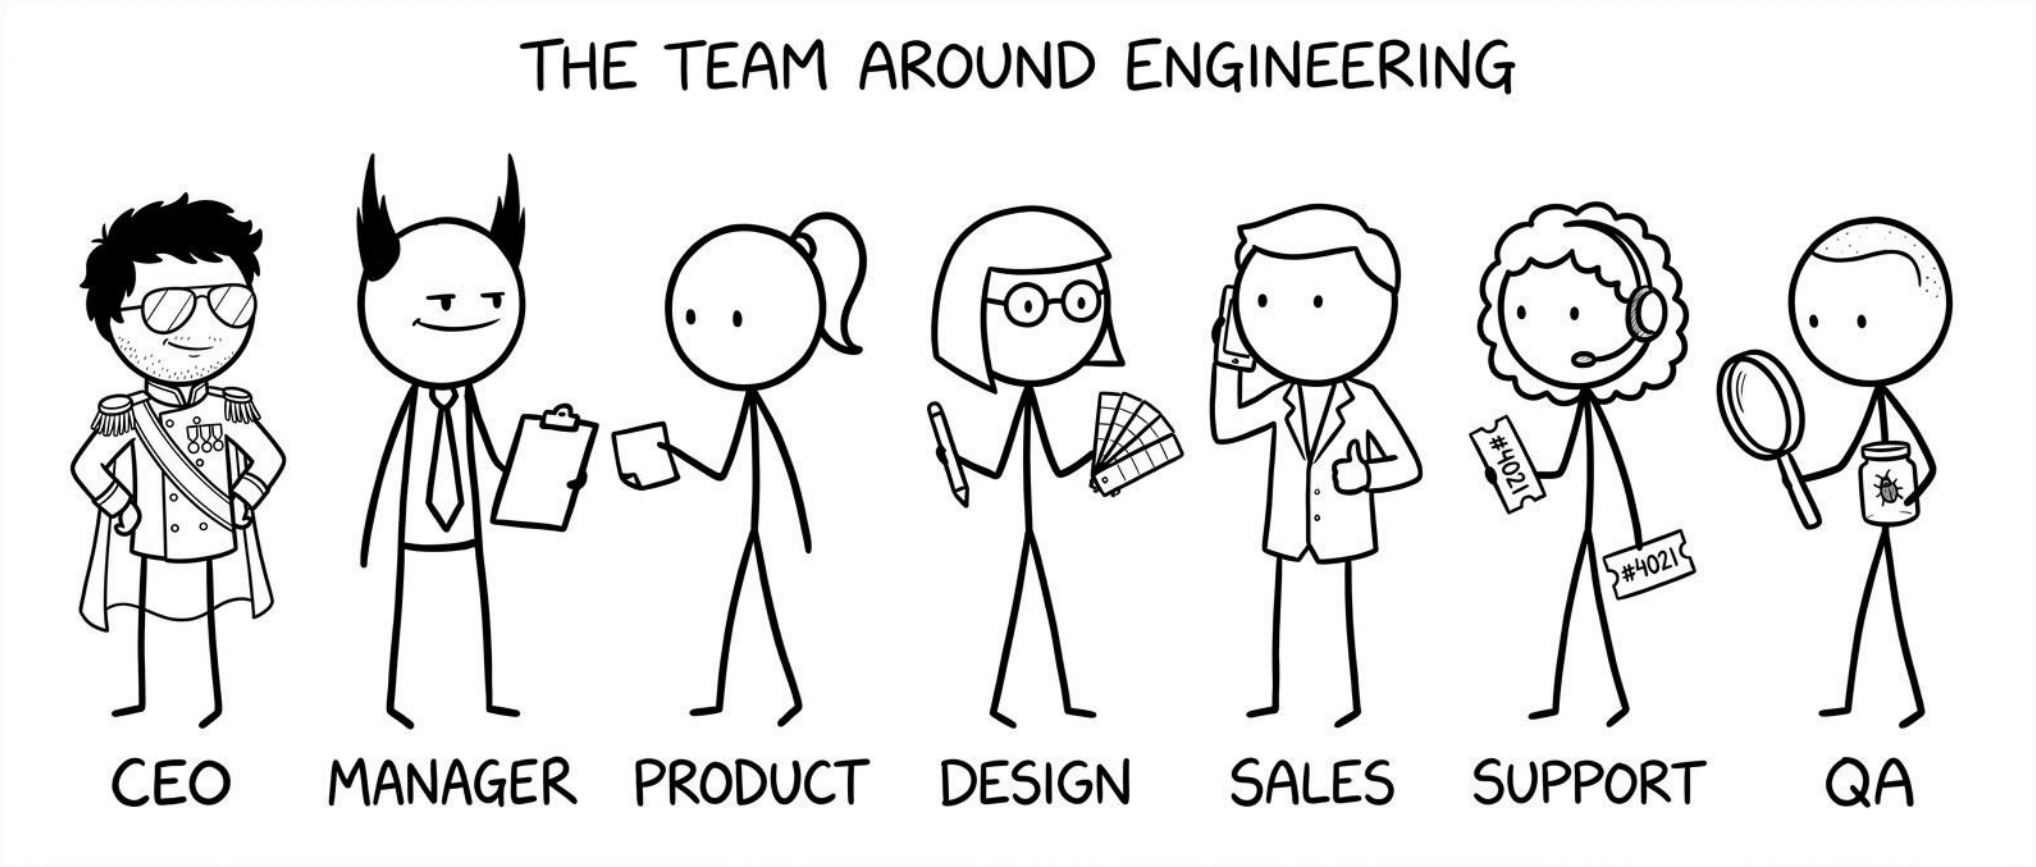

- [x] **DIRECTION**
  Does everyone know what matters, and why?

- [x] **STRUCTURE**
  Who talks to whom? Small teams, clear owners?

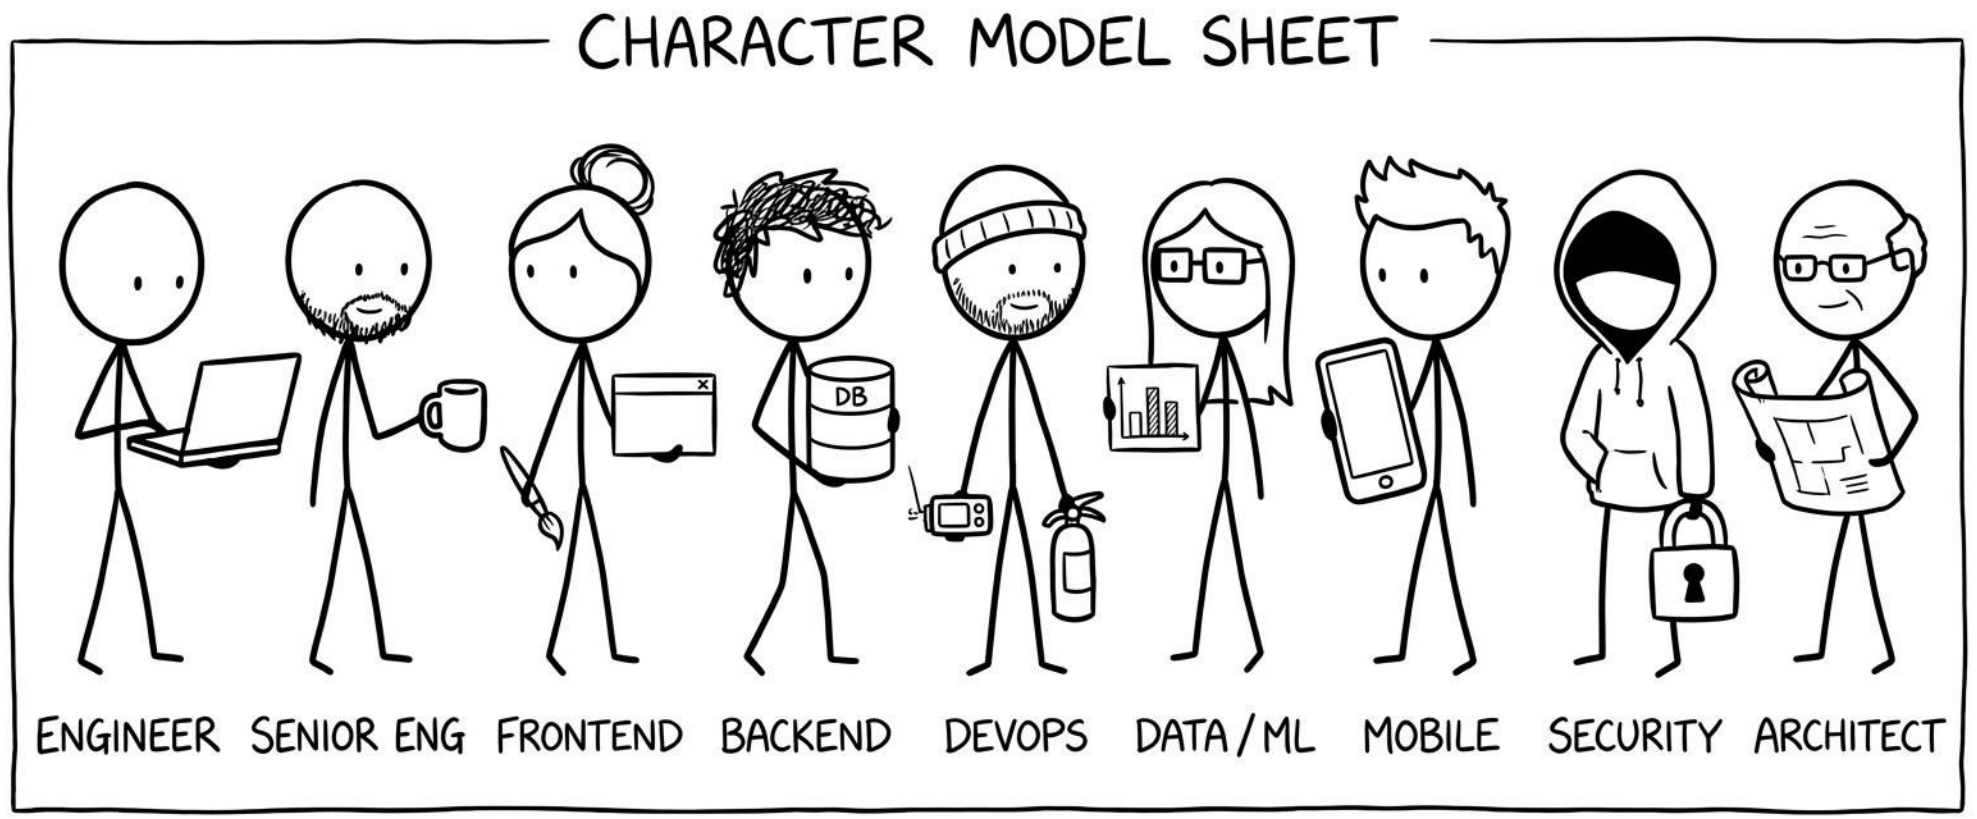

- [x] **COMMUNICATION**
  Is it written down? Syncing too much, or too little?

- [x] **KNOWLEDGE**
  Where is it stuck? What if they go on PTO tomorrow?

The EM's checklist. That's the job, in four questions. Run through them every week. When an answer is "no" or "I don't know", that's a little storm forming, and the time to break it up is now.

Meet the cast: the team around engineering. The people engineering works with every day. Each one pulls the team in a different direction: the CEO sets the vision, Product decides what to build, Design how it should feel, Sales what was promised, Support what's broken right now, and QA what's broken before anyone else finds it.

Meet the cast: the engineers. "Engineer" isn't one job. Frontend builds what you see, backend what you don't, DevOps keeps it running at 3am, Data/ML turns data into decisions, Mobile lives in the app stores, Security assumes everyone is an attacker, and the Architect worries about how it all fits together in two years.

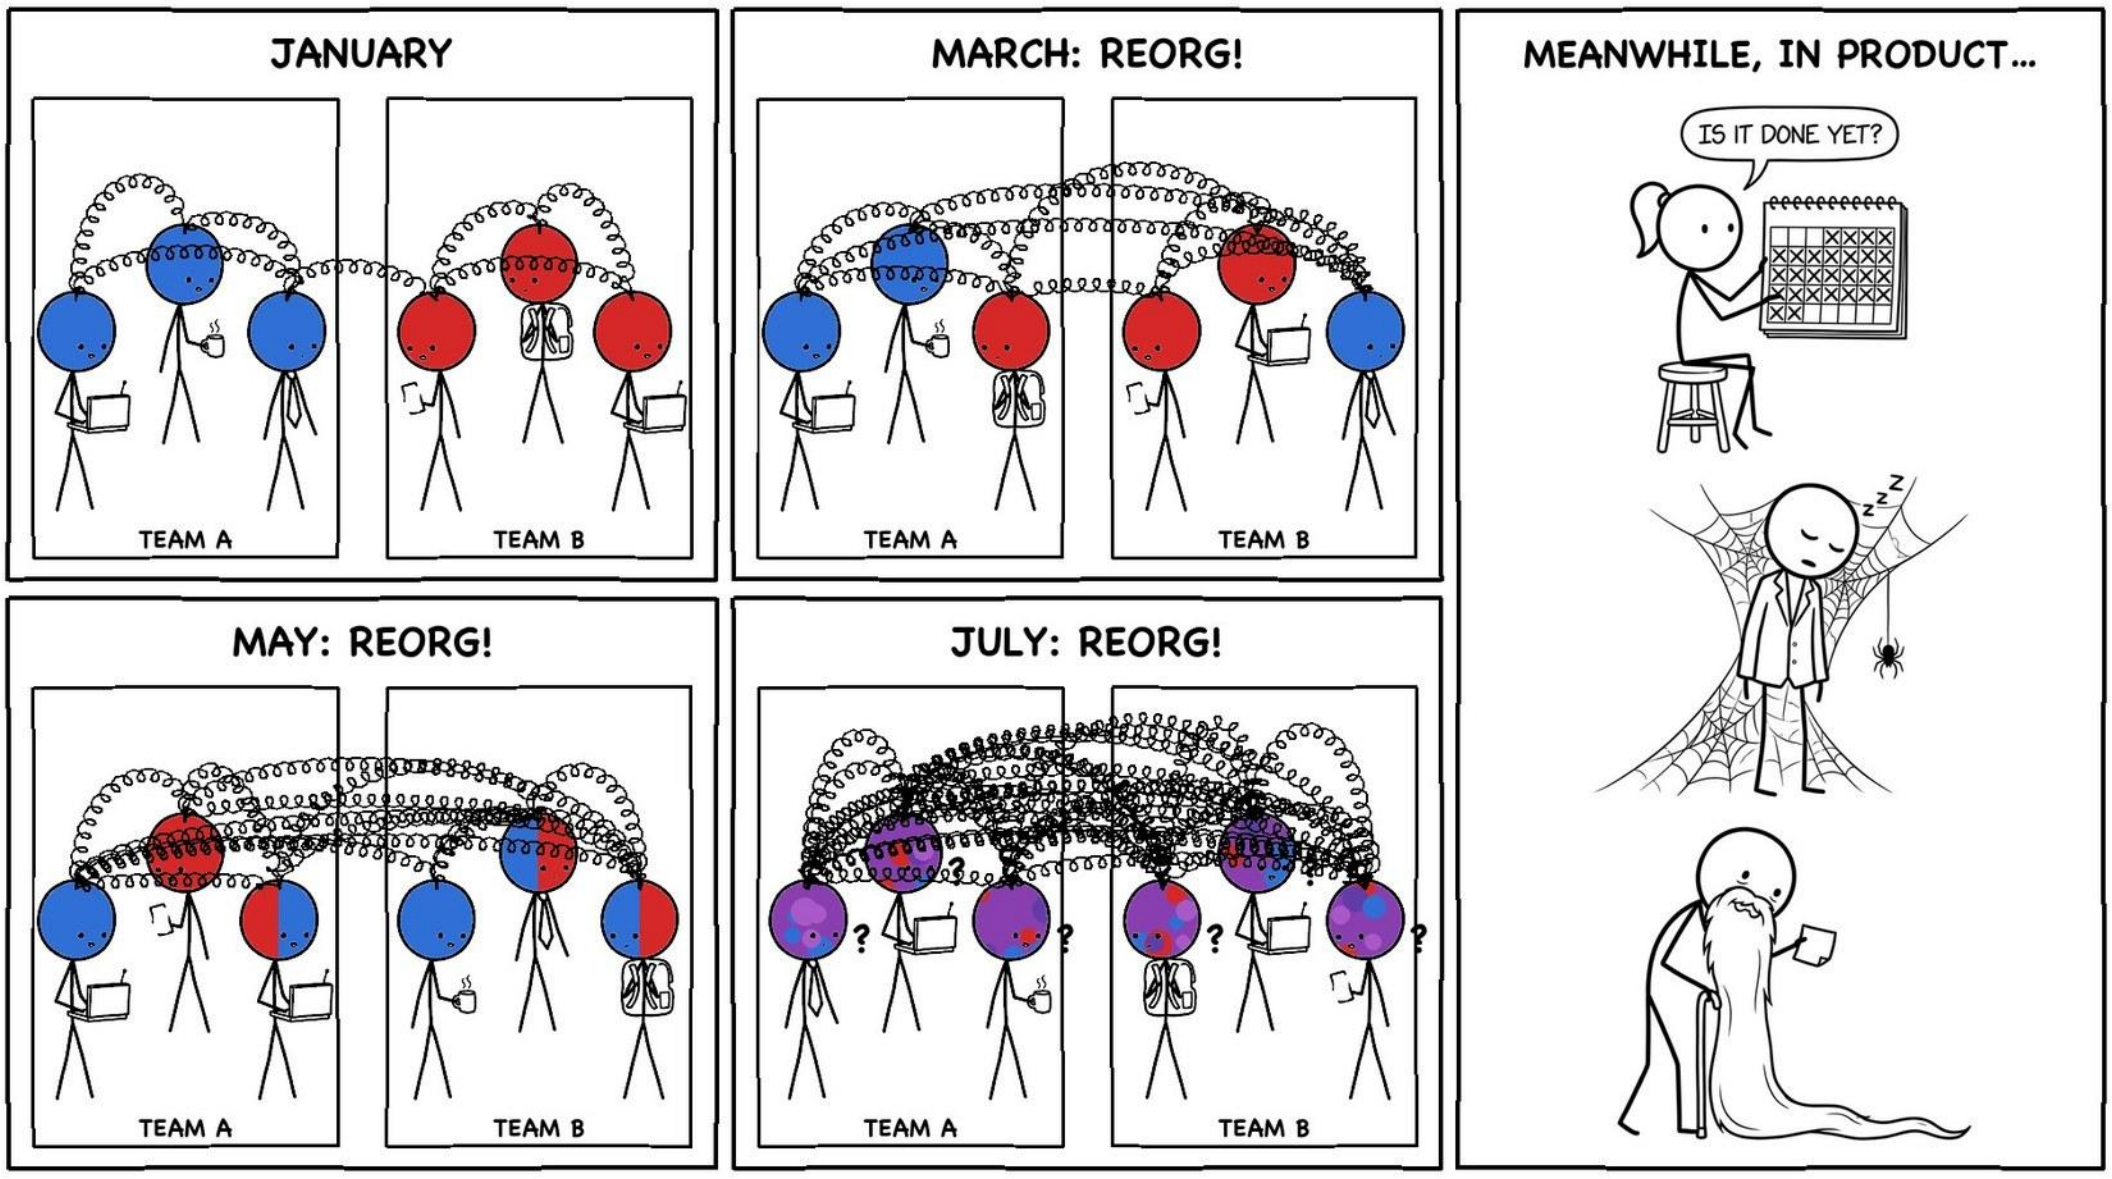

APPENDIX

Extra Slides

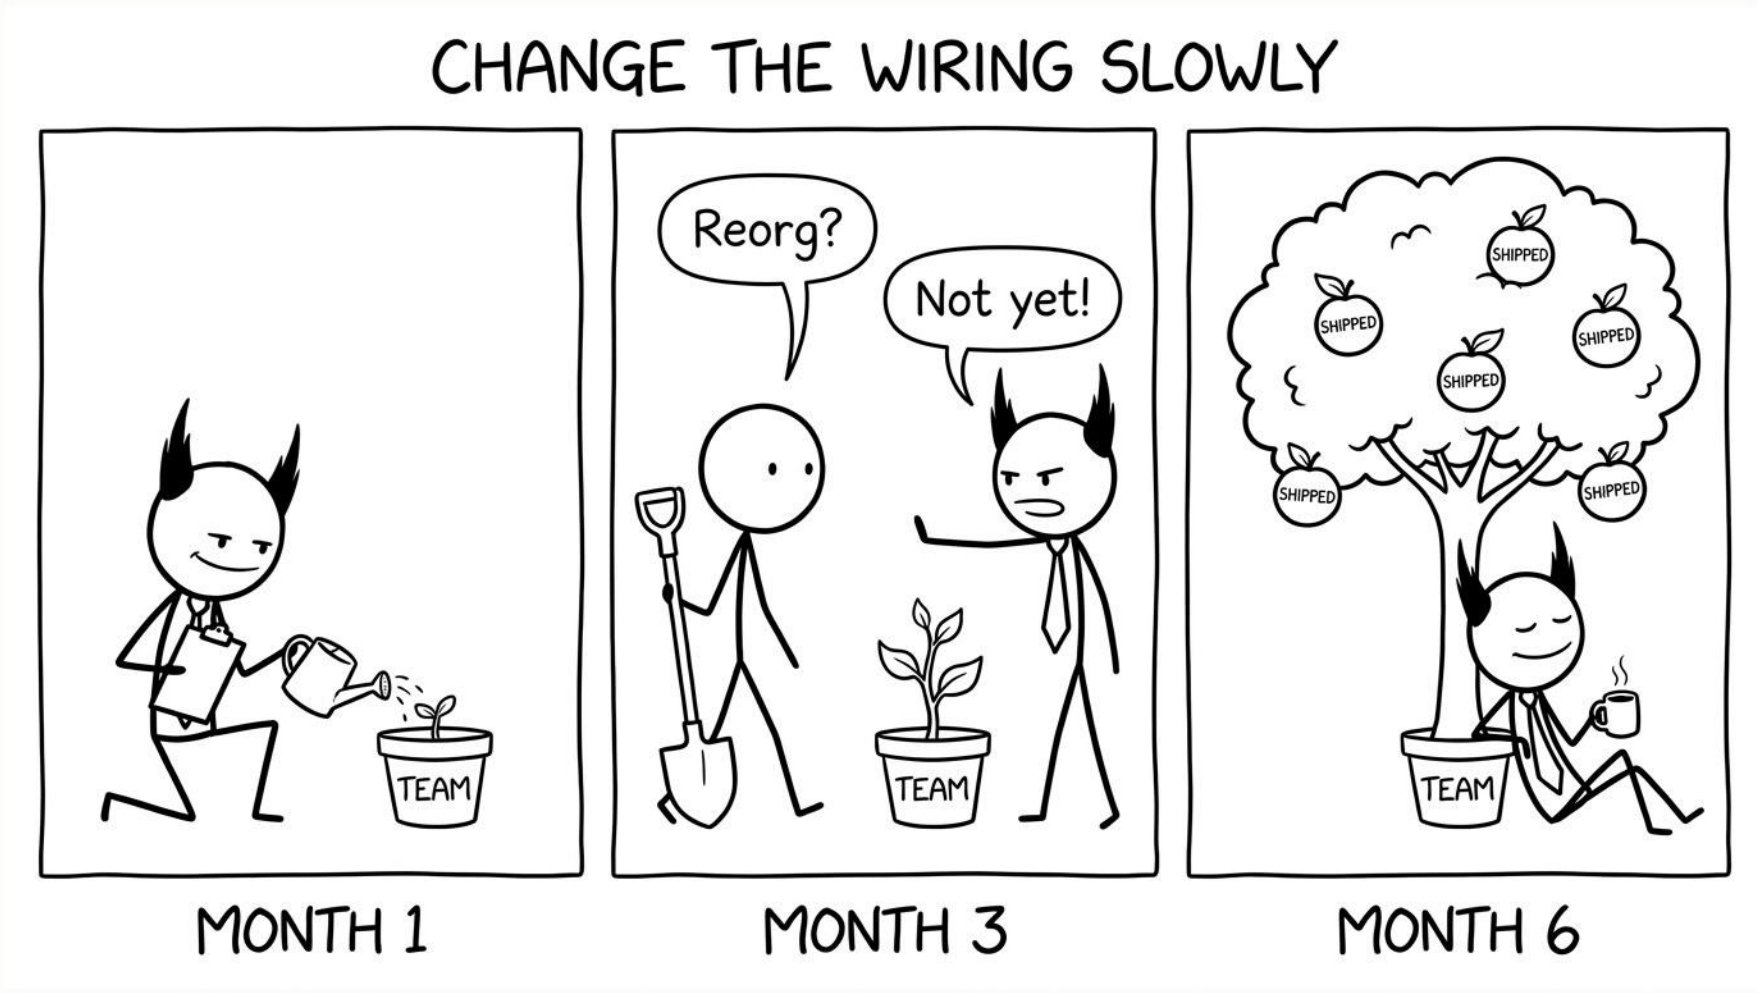

Not usually shown

Appendix. Backup slides, kept for questions. Not part of the normal talk.

Reorg Whiplash

Reorg whiplash. You can't change things too fast, because people need time to build relationships and transfer knowledge.

Change the wiring slowly. Relationships and shared knowledge take months to grow. Before the next reorg, ask whether the last one has had time to take root. Change the wiring when the goals change, not every quarter.
